Report for North Star Magnetite Project

Geochemical Assessment

November 2012

INFRASTRUCTURE | MINING & INDUSTRY | DEFENCE | PROPERTY & BUILDINGS | ENVIRONMENT

This North Star Magnetite Report *("Report"):*

1. *has been prepared by GHD Pty Ltd ("GHD") for Fortescue Metals Group;*
2. *may only be used and relied on by Fortescue Metals Group;*
3. *must not be copied to, used by, or relied on by any person other than Fortescue Metals Group without the prior written consent of GHD;*

GHD and its servants, employees and officers otherwise expressly disclaim responsibility to any person other than Fortescue Metals *arising from or in connection with this Report.*

To the maximum extent permitted by law, all implied warranties and conditions in relation to the services provided by GHD and the Report are excluded unless they are expressly stated to apply in this Report.

The opinions, conclusions and any recommendations in this Report are based on assumptions made by GHD when undertaking services and preparing the Report ("Assumptions"), including (but not limited to):

- *All data provided by Fortescue is accurate*
- *Fortescue does not possess additional relevant information that may fundamentally alter the conclusions reached in this report if it were made available*

GHD expressly disclaims responsibility for any error in, or omission from, this Report arising from or in connection with any of the Assumptions being incorrect.

Subject to the paragraphs in this section of the Report, the opinions, conclusions and any recommendations in this Report are based on conditions encountered and information reviewed at the time of preparation.

GHD has prepared this Report on the basis of information provided by Fortescue Metals Group and others who provided information to GHD (including Government authorities)], *which GHD has not independently verified or checked ("Unverified Information") beyond the agreed scope of work.*

GHD expressly disclaims responsibility in connection with the Unverified Information, including (but not limited to) errors in, or omissions from, the Report, which were caused or contributed to by errors in, or omissions from, the Unverified Information.

1. Introduction

This document has been prepared by GHD at the request of Fortescue Metals Group (Fortescue). Fortescue has requested that GHD complete a waste geochemistry assessment for an area of the proposed mining operation at the North Star Project.

1.1 Project Description

Fortescue is proposing to undertake mine development activities at its North Star Project (the Project). The Site is located within the North Star/Glacier Valley, approximately 95 km from Port Hedland and 25 km east of the existing Fortescue rail line within the Pilbara region of Western Australia. The North Star project area is located with the tenements of E45/2510 and E45/2535.

The North Star Operations will involve mining of mainly magnetite ore using conventional open pit methods (i.e. a combination of free digging and drill and blast techniques will be used for pre-stripping and ore extraction). Ore from the North Star pit will be processed through a magnetic separation process to produce an iron ore concentrate suitable for sale. It is expected that about 315 Mt of concentrate will be produced over the life of the operation.

The North Star deposit will be mined to a maximum depth of approximately 500 m below ground level (bgl). Trucks will transport ore to the Run of Mine (ROM) Pad while waste rock and overburden will be transported to the waste rock dump (WRD) located to the east of the pit.

It is estimated that the project will produce 315 Mt of magnetic concentrate over a production life of 45 years. The project is expected to generate approximately 913 Mt of waste rock, 180 Mt of dry tailings and 560 Mt of wet tailings over the life of the mining operations. Ore is to be accessed from the south-eastern end of the pit and transferred to crushers located to the south-west of the pit. Concentrated ore slurry will be pumped to Port Hedland for shipping.

The majority of the mine waste generated by the project will be stored in a single waste landform located along the eastern perimeter of the proposed pit. Tailings will be deposited within a valley located to the north of the proposed pit and waste dump. Embankments will be constructed across the western perimeter of the valley to enclose the tailings storage facility (TSF). A preliminary tailings storage design has been completed by Golder (Golder, 2011).

Additional support infrastructure will be located to the west of the pit - including roads, processing facility, slurry pipeline, accommodation camp, mess and employee facilities, workshop and temporary buildings, power supply, wastewater treatment facility and water management infrastructure.

Initial water requirement to support the construction of the mine and the slurry pipeline will be sourced from existing licensed bores located within the Fortescue rail corridor.Later water requirement for the mine operation will be sourced from the Canning Basin pipeline. The slurry pipeline will parallel the Fortescue existing rail which runs 25 km to the west of the site.

1.2 Regulatory Context

Fortescue has referred the Project to the Environmental Protection Authority (EPA). This geochemical assessment has been undertaken to meet the requirements of the Department of Mines and Petroleum (DMP)/EPA guidelines.

1.3 Geochemistry Assessment Requirement

Acid and Metalliferous Drainage (AMD) is the generation of acidic and/or metalliferous discharges as a result of the interaction between certain metal sulfide minerals, atmospheric and/or aqueous oxygen, and commensurate with the environmental geochemistry of the deposit; sometimes ferric iron. Saline drainage (SD) can also occur at circumneutral or even alkaline pH values. The resultant metals, salts and acidity from AMD and SD processes may be detrimental to the receiving environment.

Consideration of AMD risk as part of the mine planning process is therefore important in terms of:

- Cost;
- Environmental impacts;
- Long-term mine planning (closure and rehabilitation); and
- Design requirements, and optimal location and design of waste rock dumps and TSFs.

As part of this project, GHD scheduled two phases of detailed static geochemical laboratory analysis. The results of the both phases of testing are presented in Appendix G. Kinetic tests are currently underway and will be provided when they become available.

1.4 Scope of Works

The scope of work for the Project is given as follows:

- Review of selected background information relevant to the site, as provided by Fortescue;
- Review of relevant guidelines;
- Assay database geochemical assessment;
- Geochemical block modelling;
- Design and progression of a detailed geochemical testwork programme (staged approach);
- Detailed geochemistry assessment; and
- Preparation of a mine waste geochemical assessment report (this document).

This mine waste geochemical assessment report has been prepared with reference to the following documents:

- AMIRA 2002. Project P387A Prediction & Kinetic Control of Acid Mine Drainage - ARD Test Handbook. April 2002. AMIRA International Limited, Melbourne.
- ANZECC & ARMCANZ 2000. Australian and New Zealand Guidelines for Fresh and Marine Water Quality. Australian and New Zealand Environment and Conservation Council (ANZECC) and Agriculture and Resource Management Council of Australia and New Zealand (ARMCANZ).
- DITR 2007. Managing Acid and Metalliferous Drainage. Manual in the Leading Practice Sustainable Development Program for the Mining Industry series. Department of Industry, Tourism and Resources, (DITR) Canberra. February 2007.
- INAP 2009. Global Acid Rock Drainage Guide (GARD Guide) http://www.inap.com.au/GARDGuide.htm The International Network for Acid Prevention.

1.5 General Assessment Approach

Based on previous project experience, and with reference to the issues identified by the GHD/Fortescue project teams to date, the assessment approach taken by GHD includes the following tasks:

- Identify data requirements;
- Complete geochemical characterisation of waste and ore materials;
- Determine conceptual volume of Potentially Acid Forming (PAF) material;
- Determine spatial distribution of PAF material within the pit shells;
- Determine dewatering risks (related to AMD); and
- Determine long term management risks (e.g. waste storage, management of PAF material, dewatering, pit lake geochemistry).

2. Acid Rock Drainage and Acid and Metalliferous Drainage

2.1 General

As noted earlier, Acid and Metalliferous Drainage (AMD) is the generation of acidic and/or metalliferous discharges as a result of the interaction between certain metal sulfide minerals, atmospheric and/or aqueous oxygen, and commensurate with the environmental geochemistry of the deposit; sometimes ferric iron. Activities such as mining, which involve the excavation of rocks that may contain these sulfide bearing minerals, may increase the risk of AMD. The drainage resulting from metal sulfide mineral reactions as described above is generally acidic with elevated concentrations of dissolved heavy metals and salts. AMD can also be known as Acid Mine Drainage (AMD) and/or Acid Rock Drainage (ARD).

It should also be noted that circumneutral metalliferous and/or saline drainage (metalliferous and saline drainage respectively) can occur depending on a range of geoenvironmental parameters, which can be just as difficult to manage as AMD once the oxidation reactions have commenced.

For the purposes of this report, GHD is using the descriptor Acid and Metalliferous Drainage (AMD) to describe drainage water with acidic pH values, elevated metals concentrations and potentially, elevated salts such as sulfate.

For the purposes of AMD management, it is deemed important to understand that multiple factors interact to affect the oxidation rate of sulfide bearing minerals. These include chemical, physical and biological factors which should all be understood as best as is possible in order to prepare an appropriate AMD management strategy as required.

AMD can pose a significant risk to mine environmental compliance. As it is a self-limiting reaction, once the AMD process has commenced, it is often difficult to stop until either all the oxygen, water or sulfide source has been exhausted, as applicable to each site.

3. Environmental Setting

3.1 Location

The North Star Magnetite Project area (herein referred to as the 'Project area') is situated within the north-central Pilbara region, approximately 100 km south of Port Hedland and 25 km east of the FMG Port Hedland – Newman railway line. The Project area encompasses Fortescue Mining tenements M45/1180, M45/1181, M45/1182, M45/1183, M45/1184, M45/1211, M451212, M45 1213, Miscellaneous Licence tenement L45/276 and Exploration tenements E45/2510 and E45/3084.

The Project area is located within a highly dissected peneplain, characterised by a complex mosaic of geology and landforms. Dominating the site is the north-south strike ridge hosting the North Star and Glacial Valley deposits and the extensive valley units identified as potential TSF sites. Local topographical relief ranges from approximately 220 m to 420 m. The proposed ore transport corridor extends west from the southern extent of the mine area to the Fortescue rail line. The route traverses a series of ephemeral flow lines (including the Turner River), valleys, gentle plains, rises and low hills.

A number of local prospects and potential mining operations surround the project area. No mines are currently operational within the immediate vicinity of the site. The nearest Department of Environment and Conservation estate is Munagaroona Range Nature Reserve (Reserve No 31429) which lies approximately 72 km to the south-west of the Project area.

3.2 Climate

The Pilbara Region of Western Australia experiences an arid-tropical climate with two distinct seasons; a hot summer from October to April and a mild winter from May to September (Gentilli, 1972). Annual evaporation exceeds rainfall by as much as 2,500 mm per year. Seasonally low but unreliable rainfall, together with high temperatures and high diurnal temperature variations, are also characteristic climatic features of the region. This region has in the past experienced no rainfall in any month of the year, which is typical of a desert climate (Beard 1975).

The majority of the Pilbara has a bimodal rainfall distribution, resulting in two rainfall maxima per year. From January to March, rain results from storms penetrating from the north, producing sporadic and intense thunderstorms. Tropical cyclones and depressions moving southwards from northern Australian waters also cause heavy rainfall events. From May to June cold fronts move easterly across Western Australia and may occasionally reach the Pilbara Region. These fronts produce light winter rains that are generally ineffective for extensive plant growth. Surface water can be found in some pools and springs in the Pilbara Region all year round, although watercourses only flow briefly due to the short wet season.

The mean maximum daily temperature recorded at Marble Bar (approximately 90 km to the east) is 35.5 degrees Celsius. The mean annual rainfall is 354.2 mm with high variability, annual totals range from 44.9 to 417.4 mm, and the maximum recorded rainfall is 646.8 mm (Worley Parsons 2012). Mean annual daily evaporation recorded at Marble Bar (BoM Site ID4020) located 73 km to the west of the project site was 8.7 mm (records between 1968-1988). High evaporation rates such as these may limit rainfall recharge to groundwater, with the exception of high intensity rainfall events.

3.3 Geology

3.3.1 Regional

The Project area lies within the Pilbara Craton, a Pre Cambrian tectonic unit comprising granitic, sedimentary and volcanic rocks (Hickman 1983). Geology is dominated by the ancient granite-greenstone terrane, occurring as broad expanses of granitoid rocks interspersed with arcuate and linear belts of greenstone formations (Van Vreeswyk *et al.* 2004).

The North Star deposit is located within the north-western portion of the Pincunah Hill Formation of the George Creek Group, on the western limb of the Pilgangoora Syncline (Van Kranendonk 2000). The folding has curved axial traces and form isolated structures bound by sinistral fault splay. Stratigraphic variation between the fault bounded blocks suggests syndepositional horst-graben structures (Van Kranendonk 2000). Deformation and metamorphism has been observed to increase in intensity to the north west of the George Creek Group (Blewett and Champion, 2005).

3.3.2 Local

Magnetite mineralisation in the North Star area is mainly confined to the Banded Iron Formation (BIF), a member of the Pincunah Formation. The stratigraphic thickness of BIF varies from 350 to over 450 m, forming a flat-topped north-south strike ridge about 500–800 m wide and 80–120 m high. The strata strikes north-south and dips subvertically from approximately 80^{o} west to 70^{o} east, and small scale folding is common (Snowden 2010). The most significant fault in the region of the North Star deposit is a sinistral strike-slip north-northeast to south-southwest structure located 3-5km east of the deposit (Van Kranendonk 2000).Local mine scale faults transect the project area on a north easterly strike (Snowden 2010), which separates the deposit into two main ore domains.

Current knowledge indicates that the Pincunah BIF extends to a minimum depth of 300 m and remains open at depth. It is highly likely that the hematite and magnetite ore body extends below 300 m depth, with additional reserves only constrained by the economics of mining (FMG 2011).

The western sequence (Hanging Wall) of the BIF is a sequence of poorly exposed shales up to 500 m thick. The contact between the shales and BIF forms a prominent cliff which is likely to be sheared and faulted (FMG 2010).

The eastern sequence (Footwall) of the BIF comprises a 400 m thick interbedded sequence of shales, mudstones, cherts, BIF and quartzite beds, each typically 1–20 m thick. Stratigraphically, this unit comprises the upper part of the Pincunah Formation, and forms the eastern half of the ridge (FMG 2010). It is likely to be more competent than the hanging wall given the chert and quartzite component.

The geology of the deposit is shown in plan view in Figure 1 and a generalised cross section is shown in Figure 2.

Iron mineralisation at North Star occurs within the BIF member of the Pincunah Formation. The BIF has been divided into the following units based on physical and geochemical characteristics:

- Oxide: Top 30–50 m of the BIF below ground surface where magnetite (Fe_3O_4) has been oxidised to hematite (Fe_2O_3) and goethite (FeO (OH)) is also a major mineral. The partially oxidised outcrop of the BIF yields magnetic susceptibility measurements of 1000 to 10,000 x 105 SI units with isolated highs up to 30,000 x 105 SI units (Fortescue 2011);

- Grey: Significant magnetite ore at North Star. The unit is dipping sub vertically;
- Green: The sub vertically dipping magnetite unit lies to the east of the central Grey BIF. This Green BIF has variable magnetic susceptibility and high Na_2O than the surrounding units;
- Blue: This sub vertically dipping magnetite unit lies to the east of the central Grey BIF. This Blue BIF unit has variable magnetic susceptibility and shale content; and
- Red: This magnetite unit only occurs in the southern area of the North Star area and it is distinguished by its red colour from abundance of jasper.

The BIF deposit is displaced by a vertical fault which separates the deposit into two main ore domains. Based on the current mineral resource statement produced by Golder (2011), the domains are termed North and South BIF which describes the position of the BIF relative to the fault.

3.4 Preliminary Geochemical Assessment

Waste characterisation investigations were carried out by Worley Parsons (2012) which involved the collection and laboratory analysis of samples of material from the exploration drilling programme. 24 samples were collected from holes drilled in the BIF, the eastern Footwall and the western Hanging Wall. The results indicate that:

- Calculated values of Maximum Potential Acidity (MPA) ranged between 2-113kg H_2SO_4/t. The shale sample from the Hanging Wall had the highest mean and median sulfur values, a BIF sample with high pyrite content recorded the highest sulfur content;
- Acid Neutralising Capacity (ANC) ranged between 15kg H_2SO_4/t (BIF with pyrite) to 40kg H_2SO_4/t (Shale);
- Net Acid Producing Potential (NAPP) results indicate 12 samples are PAF, eight were samples of shale and four of BIF;
- The Acid Neutralising Capacity/Maximum Potential Acidity (ANC/MPA) ratio was less than two in 17 samples indicating these may be PAF;
- Multi element analysis indicated that metal concentrations were generally not significantly elevated; slight enrichments (relative to global abundance index) of cadmium, chromium, cobalt and nickel were noted; and
- The Net Acid Generation (NAG) test indicated the following geochemical classifications:
    - Non Acid Forming (NAF): 10 samples; and
    - PAF: 14 samples.

The study concluded that the shale in the Hanging Wall and pyritic sequences in the BIF unit are likely to be PAF, however due to the limited amount of testing carried out, the relative amount of material within these lithologies that may be PAF was not determined.

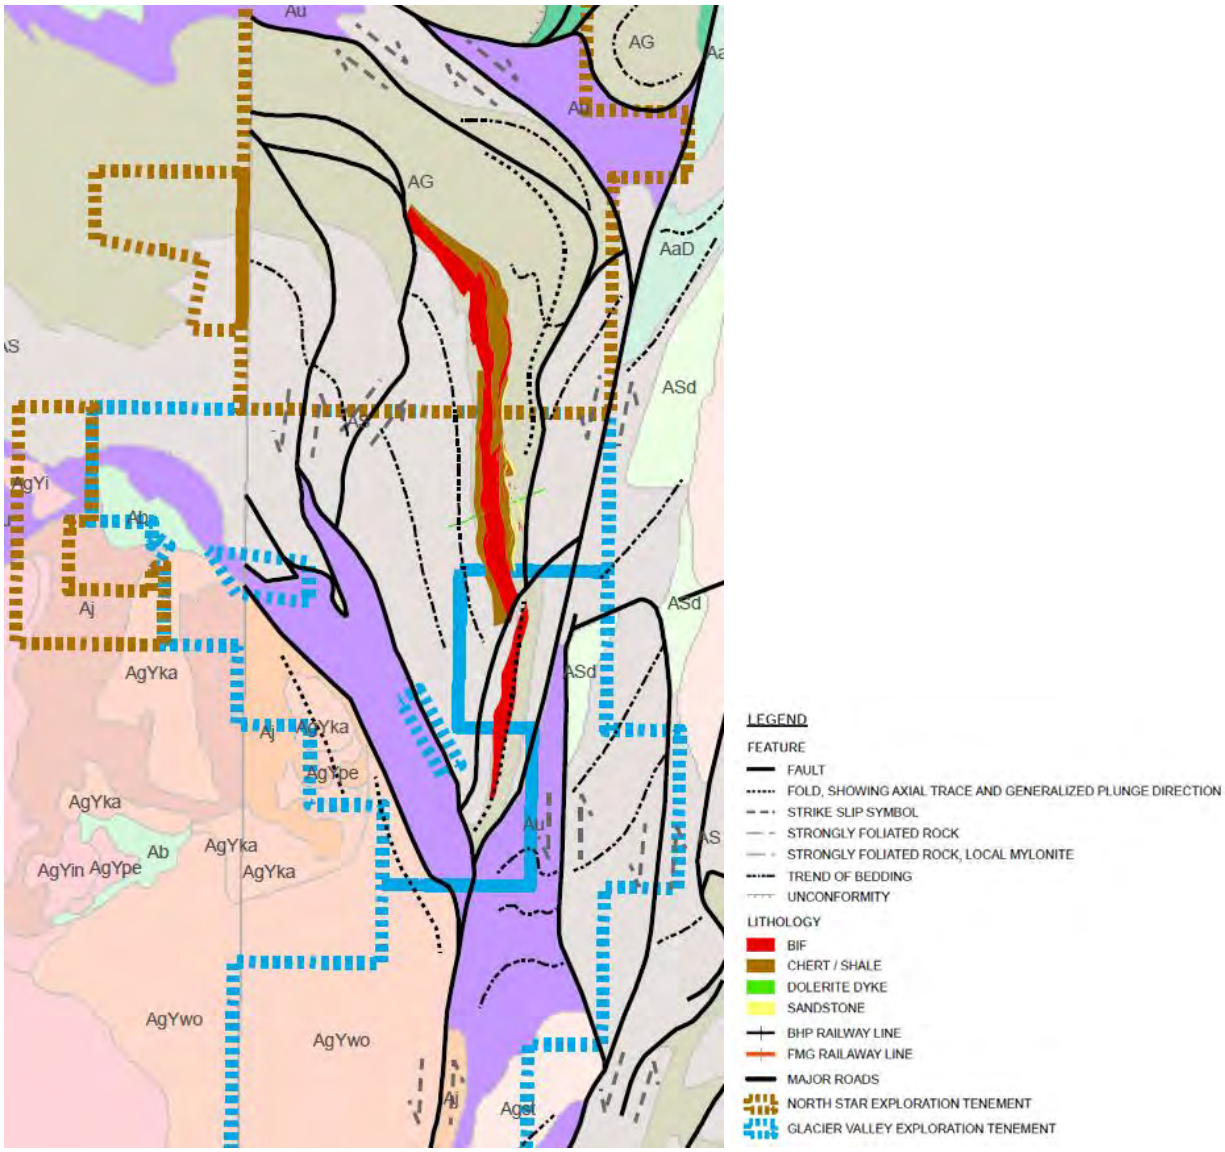

Figure 1 Local Geology (Extract from Worley Parsons, 2012)

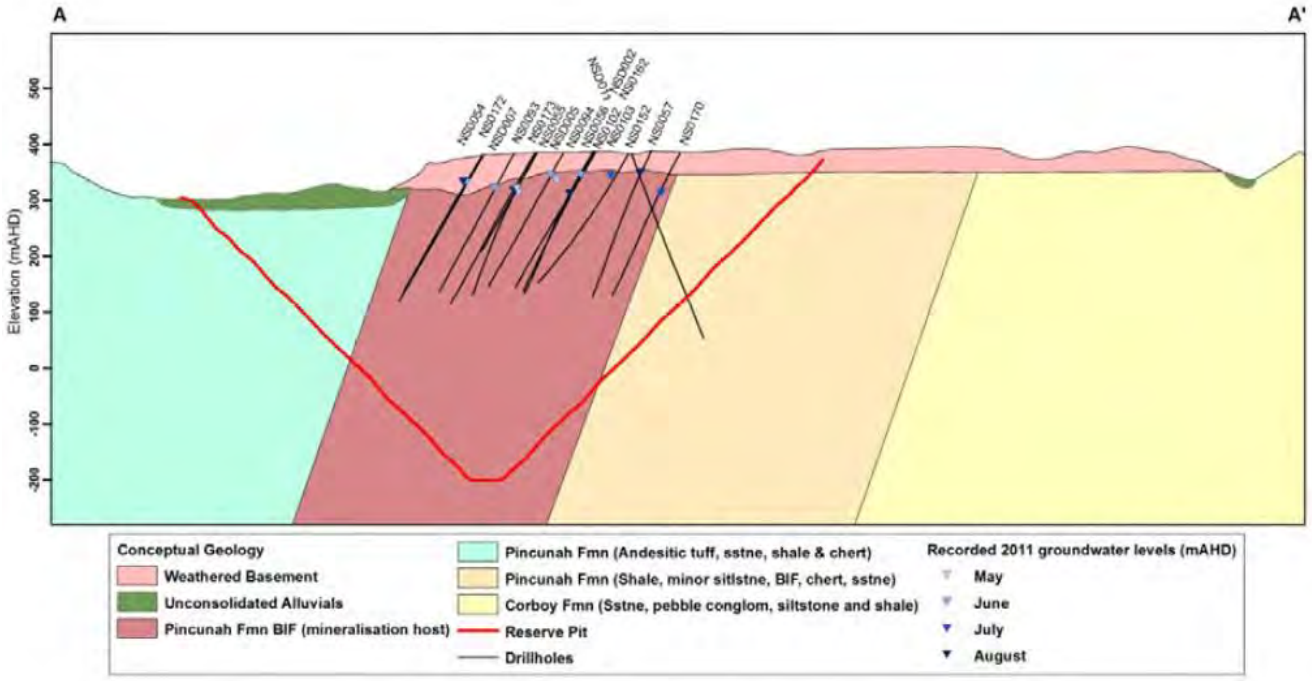

Figure 2 Generalised Geological Cross Section (Extract from Worley Parsons, 2012)

3.5 Surface Hydrology

3.5.1 Regional

Watercourses in the Pilbara Region are ephemeral and flow only occasionally. Major rainfall events, generally as a result of cyclones, can cause major flows in a number of rivers almost every year between December and April. The rivers are generally dry between August and November, with only occasional short-lived flows (Worley Parsons, 2012a and 2102b). Most of the major rivers in the Pilbara Region have extensive floodplains that periodically become inundated. Surface water may be found in some pools and springs in the Pilbara region all year round.

3.5.2 Local

The assessment area straddles the Shaw River, Turner River and Strelley River catchments. The North Star/Glacial Valley plateau acts as the principle drainage divide between the Turner River to the west, Shaw River to the south east and Strelley River to the north east (Worley Parsons, 2012a and 2012b). All three river systems generally drain in a northerly direction towards the coast. Drainage on lower slopes and plains is via a network of tributary flow lines. Drainage on the hills and slopes is variable but tends to be via unidirectional flow lines and sheet flow. Sheet flow is also likely to occur on the plains following heavy rainfall events. A prominent drainage line, known as Lost Boys Creek, flows in a north west direction through the valley of the proposed northern tailings storage facility (TSF), eventually discharging into Turners Creek. Drainage along the proposed infrastructure corridor is largely defined by an unnamed drainage channel which meanders in a westerly direction across the plains of the Rocklea, Talga and Macroy land systems. All drainage lines within the Project area are ephemeral (Worley

Parsons, 2012). The main channel of the Shaw River runs in a northerly direction and is within 20 km of North Star at its closest point.

A permanent spring was observed approximately 6 km north-west of the North Star exploration camp.

3.6 Hydrogeology

3.6.1 Regional

The central Pilbara aquifers fall into three broad groups and include:

- The unconsolidated sedimentary aquifers composed of alluvium and colluvium;
- Chemically deposited aquifers (calcrete and pisolitic limonite); and
- Fractured rock aquifers.

Valley fill sedimentary deposits can be up to 200 m thick and can include clay, sand and gravel sequences sourced from alluvial outwash, river valleys and scree slopes.

Calcrete and pisolitic aquifers, characterised by karstic formations (Johnson and Wright, 2001) are capable of large groundwater yields in the region of 1,500 kL/day to 5,000 kL/day. Groundwater in these calcrete or pisolite valley-fill aquifers is generally fresh or brackish and is the most easily obtainable groundwater source.

The granitic-greenstone area of the Pilbara region generally lacks groundwater resources with the most dominant groundwater feature found in the Hamersley Basin located to the south of the proposed operation.

The Achaean granite-greenstone, characteristic of the proposed mine site, is generally overlain by thin alluvial sediments in the river valleys. Depth to water is generally 5 to 10 m below the surface in the granitic areas. Groundwater from exploration bores at the site varies between 36 m and 280 m confirming expectation of deeper groundwater levels in the greenstone formations. Groundwater occurrences within the granitic and greenstone sequences occur primarily in fractured and weathered zones along fractures and joints. Greenstone aquifers may also be located within brittle (cherty) rocks, and is fresh inland, becoming brackish towards the coast (Haig 2009). Aquifer yields are dependent on intersecting fractures and / or targeting shallow alluvium. The Pilbara and in particular the granitic-greenstone terrane is not considered a major regional groundwater resource.

3.8.2 Local

Two distinct groundwater sources are noted as being present on site by Worley Parsons (2012):

- The first in the 0 to 50 m weathered zone of the ore body; and
- The second being in the deeper part of the fracture zone which drains both the weathered zone of the deposit and the upper alluvial catchment of the adjacent groundwater zone.

Exploration drilling conducted to date has encountered little groundwater. However, available groundwater has been located in the upper weathered zone along the NNE trending fracture zone. In addition, during drilling it has been observed that the BIF, chert, and shale country rock are extremely tight and silicified which suggests low permeability and low storage capabilities (Worley Parsons 2012).

Groundwater in the region surrounding the ore deposit is thought to be predominantly hosted by rocks of primary porosity within overlying shallow unconfined Quaternary sediments, which are hydraulically connected to some secondary porosity within the weathered and fractured Achaean basement (Worley Parsons 2012).

Fortescue drill log data indicates an average standing water level (mAHD) of approximately 80 m based on provisional data from 72 bores; 30 of which intercepted groundwater. However, groundwater surface elevation data during exploration drilling is not considered to be representative of the formations in which they were observed, as water contained in the bore holes is considered to be remnant from drilling (Worley Parsons 2012).

There remains the potential for perched aquifers to be present in the weathered zone due to compartmentalisation of groundwater within the sub-vertical bedding planes. Groundwater springs have been observed in the north-east of the site which may indicate the presence of a perched water table, or alternatively, an aquifer residing above the lower water table (Worley Parsons 2012).

Based on the hydrogeological investigations completed to date, it does not seem likely that a significant groundwater body will be encountered as a result of the proposed mining activities. Some dewatering may be required to enable open pit mining based as a result of the presence of groundwater in fracture/sheer zones however based on the findings of the Worley Parsons (2012) report.

Groundwater quality, tested from two water supply bores and one surface source indicates generally good quality, with the following observations being made:

- Chromium (Cr), copper (Cu), vanadium (V) and zinc (Zn) are above ANZECC guidelines in more than one sample (>50% of samples);
- Nitrate levels are above ANZECC guidelines in both groundwater samples; and
- Only one measured analyte (Cu) is above ANZECC guidelines in the surface water sample.

3.7 Environmentally Sensitive Areas

The Department of Environment and Conservation's (DEC) online Native Vegetation Viewer provides information on the location of Environmentally Sensitive Areas (ESAs), as declared by a Notice under section 51B of the Environmental Protection Act 1986 (EP Act). This database also indicates areas where low impact mineral and petroleum activities cannot occur without a Native Vegetation Clearing Permit, as defined under Schedule One of the Environmental Protection (Clearing of Native Vegetation) Regulations 2004.

The DEC's online Native Vegetation Viewer was searched to determine the location of any ESAs within the vicinity of the Study Area. No ESAs were identified.

4. Deposit Geology/Mineralogy Characterisation

4.1 Deposit Geology

Based on data provided by Fortescue for the deposit, the following geological summary is provided:

- Five main units have been identified in the geological model of the deposit, and are:
    - The BIF which comprises the ore body, separated into two units termed:
        - BIF-North; and
        - BIF-South.
    - The Hanging Wall which comprises shales of the Gorge Creek Group;
    - The Footwall which comprises shales/mudstones/cherts/quartzite and BIF; and
    - An Oxide layer which comprises approximately the top 50 m of the deposit.

GHD understands that to date the hanging wall and footwall material has not been identified as containing significant economic grades of iron ore relative to the BIF, and so are likely to be treated as waste rock during mining. Sub economic grade material will be required to be excavated from the Oxide unit as part of the pit development and so will form waste material. The Oxide layer has iron grades above 30%, and although it has lower magnetic susceptibility than the BIF, has been identified as containing economic grades of iron as this unit contains hematite. Sub economic grade material is also present within the Oxide zone, which will also require excavation for pit development and will therefore become additional waste material. The BIF units termed South and North have been identified as the economic ore materials; therefore some of this material may be processed for iron recovery.

A summary of material classification is provided in Table 1:

Table 1 Material Classification

Model unit	Majority Classification (Waste/Ore)
BIF-South	Ore
BIF-North	Ore
Hanging Wall	Waste
Footwall	Waste
Oxide	Ore

A summary table of the mineralogy of the BIF minerals is provided in Table 2. In general, the BIF contains low levels of aluminium (and therefore clay minerals), and high levels of silica. Given the BIF is magnetite and has an iron content of <40% and a silica content of >30%, processing of the material is required which will produce tailings that will be composed predominantly of silica.

Table 2 Mineralogy of the BIF Materials

Stratigraphic Unit	Fe %	SiO_2 %	Al_2O_3 %	P %	Mag Sus
Oxide	34.2	40.3	1.81	0.072	25,583
Blue BIF	31.2	40.4	1.83	0.084	29,081
Grey BIF	32.6	39.8	1.90	0.100	45,327
Red BIF	34.7	37.8	1.21	0.099	55,952
Green BIF	30.2	41.2	2.68	0.097	27,175
Mean	**32.6**	**39.9**	**1.89**	**0.090**	**36,624**

4.2 Asbestos Minerals

Based on information provided by the Fortescue, the likelihood of asbestos minerals being present in the deposit is low. No asbestos minerals have been observed to date during exploration drilling and laboratory testing.

Fortescue considers that the geochemistry of the deposit is characterised by sedimentary and acid/intermediate volcaniclastics. Such geology, when combined with low grade regional metamorphism, has resulted in a chert/siderite/stilpnomelane assemblage, devoid of amphiboles. The North Star deposit does not contain the mafic and ultramafic greenstones and dolerites that are normally associated with BIF magnetite or hematite mineral deposits. It is these mafic and ultramafic greenstones and dolerites that are generally responsible for many of the serpentinite asbestiform mineral assemblages. The greenstones also generally have a high Mg content which is not seen in the North Star geochemical signature.

Specific testing for asbestos has not been scheduled by GHD as part of this assessment on the basis that asbestos is not considered to be a key risk at this time.

4.3 Waste Streams

Being a magnetite deposit, the BIF will be processed on site as part of run-of-mine (ROM) ore beneficiation process to achieve a saleable product. Processing of the BIF ore on site is understood to comprise crushing, screening, dry magnetic separation and a wet separation processes. At this time the process is anticipated to produce the following waste products:

- Bulk waste rock (sub ecomonic grade material)
- Tailings from dry (3% moisture) magnetic separation (approximately 30% by volume of total tailings). The maximum size of dry tailings produced will be 3mm.
- Fine tailings from wet (30% moisture) separation (approximately 70% by volume).

Due to the nature of the geology, various waste rock streams will be produced throughout the life of mine. Given that economic grades of iron ore are not confined exclusively to strata identified as

"mineralised", and given the thinly bedded nature of mineralised and non-mineralised strata, there remains the possibility that some rock types other than those labelled as mineralised may be processed for mineral extraction, or some mineralised material may be lost to the waste stream. However, a bulk determination of materials which are likely to occur within the waste or ore stream has been made and is presented in Table 3:

Table 3 Waste Stream

Geologic Unit	Waste Streams
BIF-South	**Tailings: 30% dry coarse, 70% wet fine** **Minor waste rock**
BIF-North	**Tailings: 30% dry coarse, 70% wet fine** **Minor waste rock**
Hanging Wall	**Waste rock**
Footwall	**Waste rock**
Oxide	**Tailings: 100% dry coarse** **Waste rock**

4.3.1 Expected Waste Volumes

Based on the initial Mining Proposal study produced Golder (2012), the following volumes of material are expected for life of mine operations as shown in Table 4.

Table 4 Expected Volumes of Materials for Life of Mine Operations

Unit	Volume (Mt)
Waste rock	**913**
Product	**315**
Tailings (coarse dry)	**180**
Tailings (fines wet)	**540**

4.4 Summary of Potential Geochemistry Risk Based on Geology/Mineralisation

The iron minerals identified as part of the mineralisation of the Oxide unit (goethite, hematite) are predominantly secondary iron minerals including oxides and oxyhydroxides. Generally, such minerals do not present a high AMD risk as they are typically stable in oxidising circumneutral environments, similar to those in which they formed.

The fresh BIF materials, and shale bands in the Hanging Wall and Footwall that lie under the oxide ore body may contain pyrite within shale bands (pyrite is indicated in localised areas from logging records supplied by FMG), given the material has not been subject to oxidisation. Significant sulphide

mineralisation (for example hydrothermal primary massive sulphides) is not known to occur within the deposit (based on drilling completed to date) therefore the pyrite is likely to occur in thin and localised bands.

Units of pyritic shale and some fresh BIF have been classified as PAF to date by the initial geochemistry assessment carried out by Worley Parsons, and may therefore pose a potential AMD risk. A summary of the potential geochemical risk by lithology is given in Table 5.

Table 5 Summary Potential Geochemical Risk by Lithology

Lithological unit	Potential acidity risk	Potential metalliferous risk	Potential saline drainage or dispersion risk
Oxide	Low given leached and oxidised nature of materials.	Low (excluding iron) given leached and oxidised nature of materials, iron oxide/hydroxide minerals present which are stable in oxidising conditions.	Low given low clay content of material and leached and oxidised nature of materials.
BIF-south	Low-Medium based on depositional environment (shale bands are potential hosts for pyrite) and un-oxidised nature of material. Pyrite, if present, likely to be found in thin and localised bands. Preliminary geochemical testing confirms some PAF material present as a result of pyrite mineralisation.	Low-Medium (excluding iron) given lithological composition (BIF/chert), potential for enrichment of metals in shale bands. Preliminary geochemical testing indicates base/heavy metals not significantly enriched.	Very low given low clay content of material (competent silica rich host rock).
Footwall	Low-Medium based on depositional environment (shales are potential hosts for pyrite) and un-oxidised nature of material.	Low-Medium (excluding iron) given lack of mineralisation noted, potential for enrichment of metals in shale bands. Preliminary geochemical testing indicates base/heavy metals not significantly enriched.	Low-Medium given general low clay content of material, shale units present have potentially higher dispersive risk.
Hanging Wall	Medium-High based on depositional environment (shales are potential hosts for pyrite) and un-oxidised nature of material. Preliminary geochemical testing indicates that PAF material present as a result of pyrite mineralisation.	Low-Medium (excluding iron) given lack of mineralisation noted, potential for enrichment of metals in shale bands. Preliminary geochemical testing indicates base/heavy metals not significantly enriched.	Medium, potentially large proportion of shale units that may have dispersive risk.

Based on a high level review of geological and mineralogical data for the lithology types identified in the hematite pit shell, sulfide bearing minerals (pyrite) may be present within the Hanging Wall, BIF and Footwall shale.

PAF materials may therefore be present in the following mine streams:

- The tailings streams (both dry and wet);
- Waste rock produced from sub economic grade BIF material;
- Waste rock produce from Hanging Wall and Footwall materials; and
- Ore stockpiles.

With respect to the risk of metalliferous and saline drainage and/or the presence of asbestos; the following preliminary conclusions are drawn:

- The potential for asbestos forming minerals to be present in materials within the deposit is considered to be low at this time;
- The potential for metalliferous drainage is not considered to be high given that the mineralisation observed is not commonly associated with high concentrations of heavy metals (for example primary base metal sulfides), and preliminary geochemical testing indicates base/heavy metal content is not enriched;
- The potential for saline drainage cannot be accurately predicted based on the mineralogical data available; however the silica rich host rocks are not likely to present a high risk of saline drainage.
- The potential dispersivity risk of the waste materials cannot be accurately predicted based on the data available. However, given the low clay content of the oxide and BIF units, the risk is considered to be very low in these geological units. Further detailed testing is required to determine the risks of dispersion in the Hanging Wall and Footwall materials.

5. Geochemical Characterisation Rational

5.1 Introduction

Due to the nature of the geology, various waste rock streams will be produced throughout the mining process. Given that economical grades of iron ore are not confined to strata identified by geological logging as “mineralised”, and given the thin bedding of mineralised and non-mineralised strata, there remains the possibility that some rock types other than those labelled from geological classification as mineralised may be processed for mineral extraction, or some mineralised material may be lost to the waste stream. Based on a preliminary assessment, the following ore and waste will be generated by the project: However, a bulk determination of materials which is likely to occur within the waste or ore stream has been made as follows:

- Ore: North and South BIF bodies, Oxide material;
- Waste rock: Hanging Wall and Footwall shales (and related mudstones, chert, quartzite and BIF), un-economic grade BIF (North and South), Oxide material;
- Waste tailings (dry and wet waste streams): BIF (North and South), Oxide material.

5.2 Geochemical Characterisation Process

The assessment approach taken by GHD based on previous project experience and liaison with the broader Fortescue project team includes the following tasks:

- Task 1: Review existing data. Task 1 included the following sub-tasks:
    - Complete high level geochemical and geophysical characterisation of existing geochemical data;
    - Incorporate existing data into the 3D geochemical model to aid with production of a targeted testing strategy; and
    - Complete a screening level assessment of the suitability of waste materials for reuse as part of planned rehabilitation.
- Task 2: Production of a static and kinetic geochemical test work strategy.
- Task 3: Undertake the static and kinetic geochemical test work strategy, including sample collection from storage and scheduling of laboratory analysis.
- Task 4: Task 4 includes the following sub-tasks:
    - Detailed analysis of the static and kinetic geochemical results ;
    - Detailed geochemical and geophysical characterisation of the waste materials; and
    - Complete a risk assessment.
- Task 5: Reporting: Production of a site wide geochemical, waste classification and acid and metalliferous drainage report.

The process outlined above is an iterative one, with the scope and scale of Tasks 3 to 5 being continually updated through the project duration based on the geochemical data interpretation completed to date and any remaining information gaps with respect to AMD risk.

5.2.1 Summary of Task 1 Works Completed to Date

At the time of writing, GHD had completed the following Task 1 scope:

- Review of existing, relevant data as provided by Fortescue;
- Completion of high level geochemical and geophysical characterisation of existing geochemical data;
- Processing of Fortescue geo assay database in Discover 3D;
- Production of a geochemical model and cross-sections in Discover 3D;
- Completion of conceptual assessment of mine waste material geochemistry and AMD risk from NAPP calculations (using Fortescue XRF assay data for Sulfur (S) and Calcium (Ca));
- Assessment of metallurgical reports to determine the likely waste streams and processing requirements for the ore; and
- Assessment of hydrogeological data to determine dewatering requirements and impacts.

As part of Task 1, analysis assessment of the AMD characteristics of the tested materials is completed by reporting the following:

- **Net Acid Producing Potential (NAPP)**

  This is a theoretical calculation based on the capacity of a sample to generate acid (MPA) and its capacity to neutralise acid (ANC). NAPP is expressed in units of kg H_2SO_4/t.

- **NAPP = MPA-ANC**

  If MPA is less than ANC, then the NAPP is negative, which indicates that the sample may have sufficient ANC to prevent acid generation. If MPA exceeds ANC then NAPP is positive which indicates the material may be acid generating.

- **ANC/MPA ratio**

  The ANC/MPA ratio is another way of analysing the acid base accounting. A positive NAPP is equivalent to an ANC/MPA ratio of less than 1, and a negative NAPP is equivalent to an ANC/MPA ratio greater than 1. The ANC/MPA ratio provides an indication of the relative margin of safety (or factor of safety) with respect to the potential for net acid generation.

5.2.2 Task 2 to 3 Works Completed to date

Tasks 2-3 comprise a detailed static and kinetic geochemical analytical test work program. The following tasks have been completed:

- Production of a detailed AMD (and materials classification) test work programme;
- Selection of analytical laboratories: ALS and SGS laboratories in Perth have been selected for analysis, both are NATA accredited for the testing scheduled;
- Selection and collection of samples from the historic drilling programme (ongoing); and

- Management of the test work programme including ongoing scheduling of testing (as required), data analysis, and data management.

Key considerations that have been taken into account when designing the static and kinetic geochemical test work programme are:

- To ensure an adequate spatial coverage of the resource; and
- To ensure representative coverage of the material types likely to be encountered.

As noted above, all samples identified and recovered to date are samples selected from existing sample material obtained from historic exploration drilling works.

At the time of writing, the sampling and analytical program had the following status:

- Selected samples (approximately 1200) have been completed for NAG testing;
- Selected samples have been scheduled for XRD (60), ICPMS metals screen (140), ABA (150), Australian Standard Leaching Protocol (ASLP) leach testing (125), NAG liquor analysis (125), acid base characterisation curve (ABCC) testing (60), kinetic NAG testing (20); and
- The majority of the results of the detailed testing have been received from the laboratory for the detailed testing at the time of writing.

5.2.3 Task 4-5 Work Completed to Date

Task 4-5 works completed at the time of writing include:

- Provisional assessment of quantitative data produced from existing AMD test work programme;
- Review of static test results received to date;
- Classification of mine waste units into either Non Acid Forming (NAF), potentially acid forming (PAF), net acid consuming (NAC), or Uncertain (UC) commensurate with analytical results;
- Determination of volumes of materials that may be PAF, NAF, UC or NAC for appropriate management of acid forming and consuming wastes, and beneficial reuse in construction and/or rehabilitation;
- Validation check of the geochemical model; and
- Preparation of waste geochemistry assessment report (this document herein).

5.2.4 Ongoing tasks

- GHD will prepare and issue an addendum document to include additional detailed test data that has not been received to date once all the laboratory results have been received and interpreted.
- Based on the results of the static testing, kinetic leach columns have been commenced for a number of samples that will run for a minimum of 6 months. To date GHD has instructed the laboratory to commence 6 leach columns.

6. High Level Geochemistry Review

6.1 Geochemical Data Set

As part of Task 1, a high level review was undertaken on available assay database data provided to GHD by Fortescue. The data was generated during on site exploration drilling (refer Appendix E). A drill hole plan showing the locations of boreholes that data has been gathered from and that lie within the drill hole database is provided as Appendix A.

It should be noted that no assay data was available for much of the Hanging Wall waste material which forms the majority of the western zone of the deposit. As a result, an assessment of the geochemistry of these materials is not possible at this time. Material in this zone comprises approximately 40% of the overall volume in the pit shell, and the majority of this zone comprises waste rock. Therefore volumes of PAF materials that may be generated by mining activities at the site have been determined based on extrapolative modelling methods.

The drill hole assay data set includes classification by geological class which in this case includes:

- Oxide;
- Footwall;
- Hanging Wall; and
- BIF-South.

The dataset also includes a classification based on magnetic susceptibility (magnetite grade) which in this case is defined as:

- Mineralised (based on Magsus >20,000); and
- Non-Mineralised (based on Magsus <20,000)

Mineralised materials are likely to represent ore materials whereas non-mineralised material is more likely to represent waste material.

6.2 Total Sulfur Statistical Distribution

The assay database (n= 21,161 samples) provided by Fortescue was analysed to determine the statistical distribution of sulfur across the site. This task showed that > 90% of sulfur assay values were below 0.3% (total sulfur) which corresponds to a theoretical maximum potential acidity (MPA) of 9 kg H_2SO_4/t (i.e. 0.3*30.6, and rounded to one decimal place).

The results indicated that material within the pit shell generally contained low levels of sulfur (< 0.3% total sulfur). Based on these results, the majority of the materials are likely to have a low risk of being PAF.

Figure 3 is a cumulative histogram for all 21,161 XRF generated (assay data) total Sulfur data points within the Magnetite project assay database.

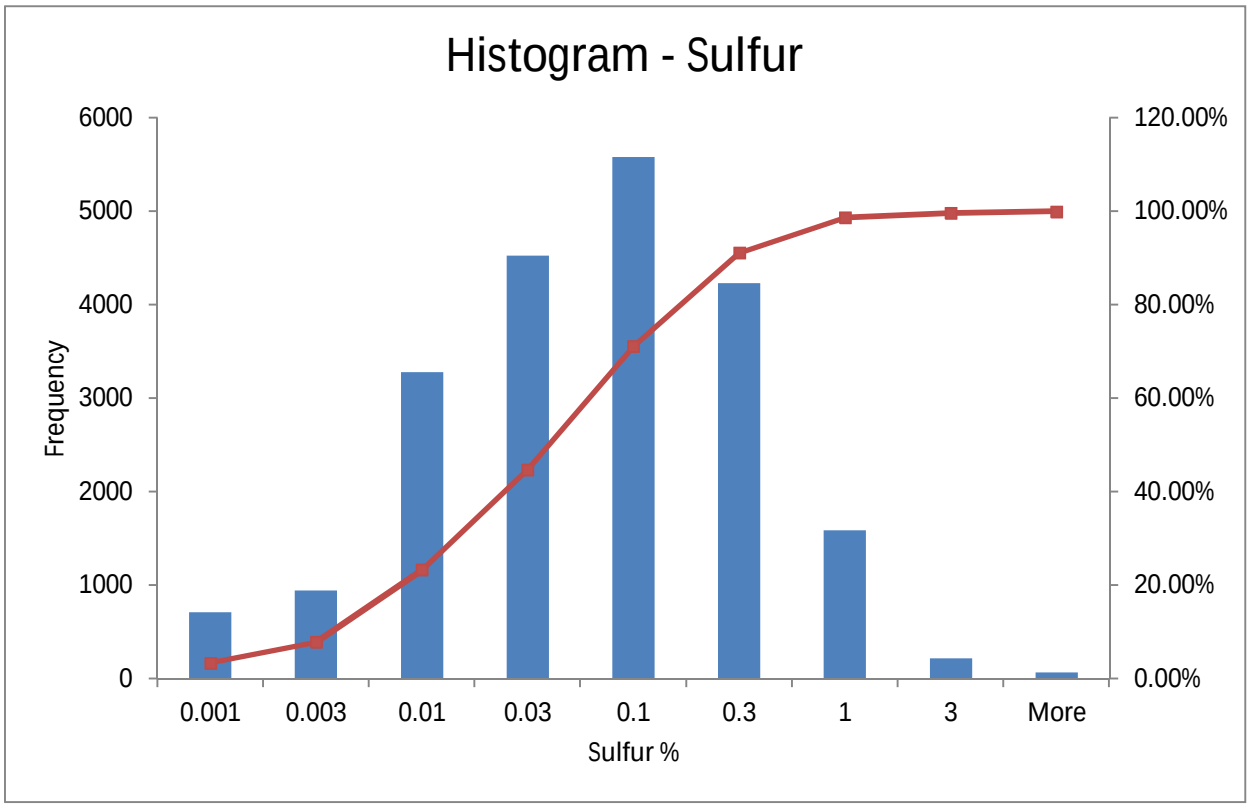

Figure 3 Cumulative histogram of all total sulfur data

Summary statistics for the 21,161 total sulfur readings are provided in Table 6.

Table 6 Sulfur Statistics (All Data)

Total sulfur (%)	
Mean	0.12%
Standard Error	0.003%
Standard Deviation	0.37
Range	19
Minimum	0.00
Maximum	19
Count	21161

Table 6 indicates that the average total sulfur value was 0.12%, with a standard deviation value of 0.37 and a range of 19. These results indicate that the deposit contains mainly low sulfur material (<0.3% total sulfur). It should be noted that the average value may be skewed by the variability in the data set. The occurrence of a small sub group of higher total sulfur material is identified by a maximum value of 19%.

6.3 Net Acid Producing Potential (NAPP)

As part of Task 1 for this Project, NAPP values have been conservatively estimated herein by assuming that all sulfur present is in the form of pyritic (FeS_2) or reactive sulfur. Using this assumption, 100% of the sulfur present is available to form acid via the following reaction:

$FeS_2 + 15/4O_2 + 7/2H_2O = Fe(OH)_3 + 2H_2SO_4$

Based on the balanced reaction stoichiometry provided above, 1% pyrite by weight translates to 30.6kg of H_2SO_4 per tonne of material (kg H_2SO_4/t). Therefore MPA is calculated by multiplying the weight of total sulfur (in %) by 30.6. As calcium carbonate ($CaCO_3$) reacts with H_2SO_4 to neutralise the acid on a 2:1 stoichiometric ratio, then it is also useful to calculate the relative acid neutralising capacity (expressed in terms of kg H_2SO_4/t equivalent) of the materials being tested based on calcium content. It is noted that a conversion factor is required to account for the fact that calcium is heavier than sulfur, and so on a molar ratio more calcium is required to achieve the correct stoichiometric ratio (the conversion factor used by GHD is 0.57). Calcium oxide (molecular weight of 56) has a higher molecular weight than sulfur (molecular weight of 32). Therefore, an appropriate calculation of relative acid neutralising capacity (kg H_2SO_4/t equivalent) requires multiplying the weight of calcium oxide (in %) by 30.6 and by a molecular weight conversion. Although other carbonate minerals may be present (for example magnesium may represent dolomite), calcium carbonates are recognised as the most readily available of the carbonate minerals and so for conservatism only calcium is considered as providing potential ANC.

The NAPP value was calculated for all 21,161 data points within the pit shell database based on relative sulfur and calcium concentrations. Results are shown in Figure 4.

A plan view of the NAPP data is given in Appendix B. On this plan, maximum values for Net Acid Producing Potential (NAPP) in any one location (i.e. the highest results at any depth at each location) are shown using a colour coded key.

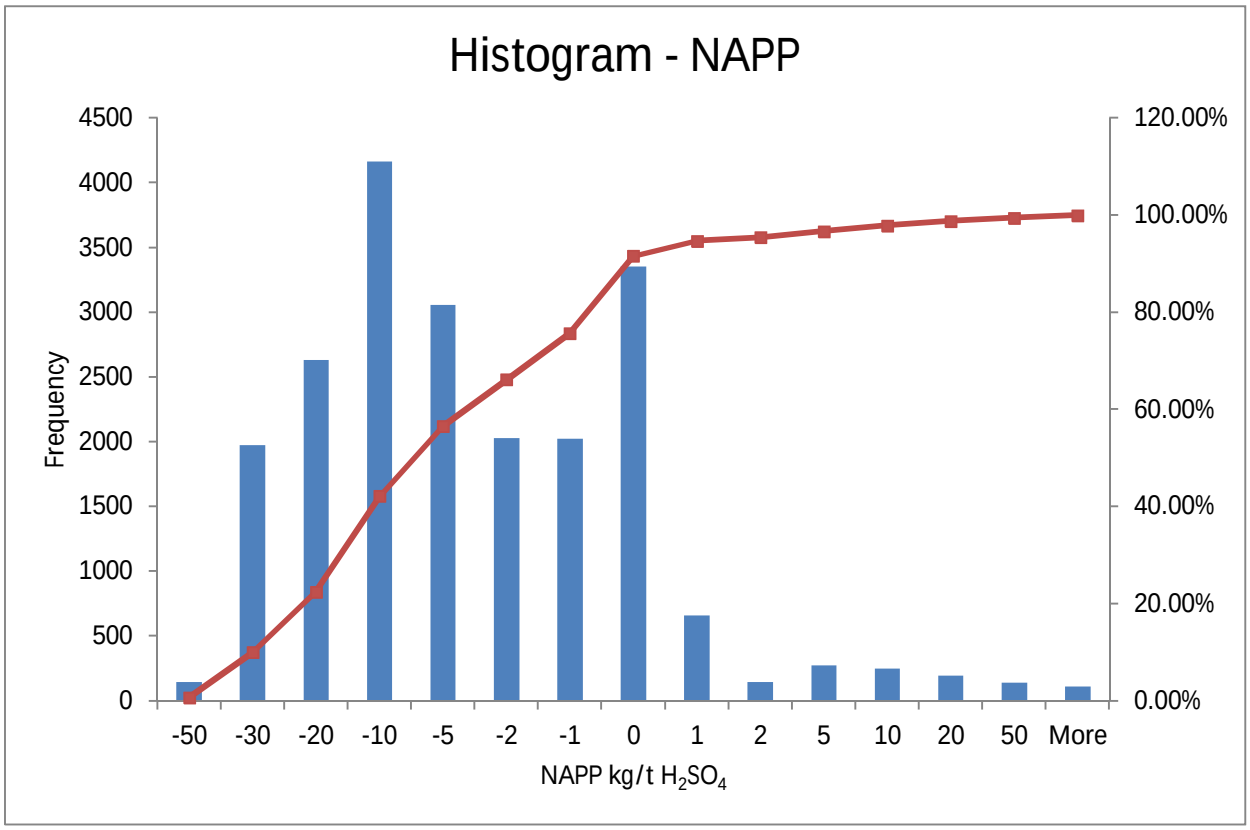

Figure 4 All data NAPP histogram

Figure 4 shows that 92% of material within the pit shell has a NAPP value < 0kg H_2SO_4/t, indicating that this material is potentially NAF (refer to Table 7). 8% of the samples returned a NAPP value > 0kg H_2SO_4/t indicating this material is potentially PAF (refer to Table 7), however of these samples 37% returned a NAPP value <1kg H_2SO_4/t indicating the acidity production potential is low.

Three main groups of material are identified on the basis of the distribution of data shown in Figure 4. These are:

- A large proportion (75%) of the dataset returned a NAPP value between -1 and -30kg H_2SO_4/t. The data appears to show normal distribution. The highest frequency of occurrence for any category was -10kg H_2SO_4/t which implies that the majority of the material has net excess total calcium relative to total sulfur.
- There is a clustering of data (29%) within the -1 to 1kg H_2SO_4/t range, which likely reflects material that is geochemically benign having low total calcium and total sulfur levels, or, that net total calcium and sulfur concentrations result in this NAPP range.
- There is a noticeable tail in the distribution ranging from 2 to > 50kg H_2SO_4/t. This represents a subset of material (5.3%) that has significantly higher total sulfur relative to total calcium levels than the majority of the dataset.

Table 7 presents the summary statistics for the NAPP data within the pit shell. From the data presented in Table 7, it appears likely that with a mean value of -10kg H_2SO_4/t, the materials in the pit are not likely to pose a high risk of producing acid from sulfide oxidation. If the calcium minerals are freely available

(i.e. present in soluble carbonate forms), then the data indicates that the materials may be theoretically slightly net acid consuming.

It is noted that these statistics are based on drill hole data which is biased towards the ore body materials as little drilling was completed into the Hanging Wall or Footwall materials. Therefore, these proportions may not be an accurate representation of the bulk properties of the total volume of material within the pit shell.

Table 7 All Data NAPP Statistics

NAPP (H_2SO_4/t)	
Mean	-10.30 (H_2SO_4/t)
Standard Error	0.11 (H_2SO_4/t)
Standard Deviation	16.73
Range	678.77
Minimum	-99.81
Maximum	578.96
Sum	-218031.84
Count	21161.00

- 91.6% of samples have a NAPP of <0kg H_2SO_4/t indicating they are not likely to be acid forming
- 8.4% of samples have a NAPP of >0kg H_2SO_4/t indicating they are potentially acid forming but at low levels
- 2.2% of samples have a NAPP of >10kg H_2SO_4/t indicating they are potentially highly acid forming

The above classification is based on the NAPP values only, and does not consider non-contributing Ca and S species.

The average NAPP values for each lithological type in the pit is:

- Oxide: -1.2kg H_2SO_4/t;
- Hanging Wall: -2.5kg H_2SO_4/t;
- BIF-North: -9.3kg H_2SO_4/t;
- Footwall: -11.7kg H_2SO_4/t; and
- BIF-South: -17.9kg H_2SO_4.

The average NAPP values calculated are negative for all materials, indicating that (on a bulk scale) are unlikely to be net acid producing.

- The oxide has a NAPP value close to 0kg H_2SO_4 indicating this material is geochemically benign having neither an excess of sulfur or calcium.
- Although the Hanging Wall material has a NAPP value close to 0kg H_2SO_4 it is not likely to be geochemically benign as the near neutral average result relates to the presence of material with an

excess of calcium as well as a significant amount of material with an excess of sulphur (NAPP value >10kg H_2SO_4).

- The BIF South material contains a small proportion of material with elevated sulphur (NAPP value >10kg H_2SO_4), however the majority of material contains an excess of calcium which results in this material having the most negative NAPP vale (-17.9 kg H_2SO_4). The BIF South material may therefore have potentially acid consuming properties on a bulk basis.

6.4 Materials Classification

The NAPP values calculated from geochemical data sourced from Fortescue's geochemical assay data base (n = 21,161 samples) were used to classify the relative AMD risk posed within the five different geological units - Oxide, BIF-South, BIF-North, Hanging Wall and Footwall. The classification system adopted for this assessment is based on the criteria set out below in Table 8:

Table 8 Material classification

Primary Geochemical Material Type	NAPP[1] (kg H_2SO_4/tonne)
Potentially Acid Forming (PAF)	> 10
Uncertain (UC)	0 – 10
Non-Acid Forming (NAF)	< 0
Acid Consuming (AC)	< -50

Material with a NAPP between 0-10 was assigned a provisional classification of UC and not PAF because of the conservative nature of the NAPP calculation. Laboratory testing utilising the NAG method was scheduled to confirm the acid generating potential of this material.

6.5 Calcium to Total Sulfur Ratios

Table 9 presents a statistical summary for the calcium: total sulfur ratio for all 21,161 samples in the assay database. In general, a ratio of < 2 may indicate that the materials do not have sufficient buffering capacity to self-regulate acidity generation, commensurate with reaction kinetics (AMIRA 2002). The results in Table 9 however, show a mean ratio of 13, with 95% of the sample returning a ratio of > 2.9 (not presented). These results may indicate that the material within the pit has significantly higher calcium to total sulfur concentrations, indicating that the units likely possess greater ANC than MPA.

[1] From Miller (1996), AMIRA (2002) and DITR (2007).

Table 9 Statistical Summary of all Ca: Total S Data

Ca:S Ratio	
Mean	**12.97**
Standard Error	**0.14**
Standard Deviation	**20.70**
Range	**532.95**
Minimum	**0.00**
Maximum	**532.95**
Sum	**274508.47**
Count	**21161.00**

The following set of Figures (5-10) show the calcium: sulfur distributions across the five lithology types within the pit area. The interpreted AMD risk from the information plotted on Figures 5 to 10 inclusive was determined as follows:

- The MPA is indicated by the horizontal lines showing total sulfur concentrations for MPA values of 1, 10 and 100kg H_2SO_4/t;
- The ANC is indicated by the vertical lines showing calcium concentrations for ANC values of 1, 10 and 100kg H_2SO_4/t equivalent;
- PAF material is indicated by samples plotting above the 2:1 calcium: total sulfur ratio line (AMIRA, 2002);
- NAF material is indicated by samples plotting below the 2:1 calcium: total sulfur ratio line;
- PAF and NAF materials are further differentiated as follows:
    - Data points plotting above the 2:1 Ca: total S line, and above the 10kg H_2SO_4/t horizontal line are likely to be PAF;
    - Data points plotting close to or above the 100kg H_2SO_4/t horizontal line are likely to be very highly PAF;
    - Data points plotting above the 2:1 Ca: total S line and between the 1 and 10kg H_2SO_4/t horizontal lines may be PAF, but are classified as low acidity generating capacity (PAF-LC);
    - Data points plotting below the 2:1 Ca: total S line and between the 1 and 10kg H_2SO_4/t ANC vertical lines are likely to be NAF; and
    - Data points plotting above the 2:1 Ca: total S line and to the right of the 10kg H_2SO_4/t ANC vertical line are likely to be NAF or net acid consuming

In general calcium concentrations were higher than total sulfur in the majority of the materials present within the pit shell area, potentially indicating that the majority of materials are not likely to be net acid forming.

A summary of the data presented in Figure 5 (and detailed in Figures 6 to 11 inclusive), indicates:

- The majority of the materials within the pit shell are NAF and may be net acid consuming, with ANC values of >10kg H_2SO_4/t ANC;
- Approximately 3% of samples have a NAPP value in excess of 10kg H_2SO_4/t;
- A small number of samples plot close to or above the 100kg H_2SO_4/t horizontal line, and are likely to be very highly PAF.

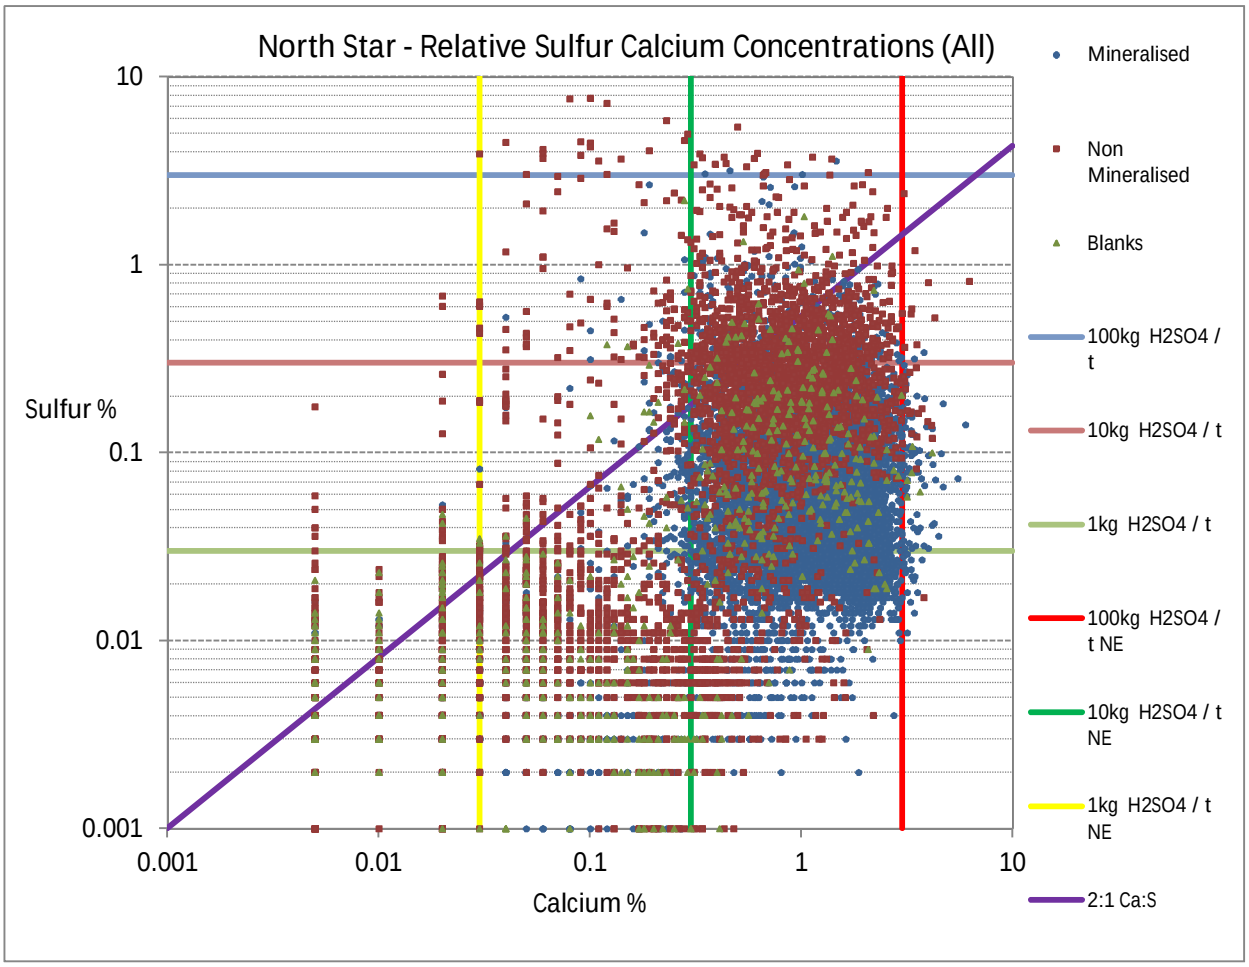

Figure 5 Relative sulfur: calcium concentrations (all data)

The assay database provided for the Footwall material (Figure 6) indicated both mineralised and non-mineralised material to be present. Based on the sulfur: calcium ratio, this material is likely to be NAF and may be NAC. A small proportion of the Footwall material plots above the 2:1 Ca: total S line, and is likely to be classified as PAF.

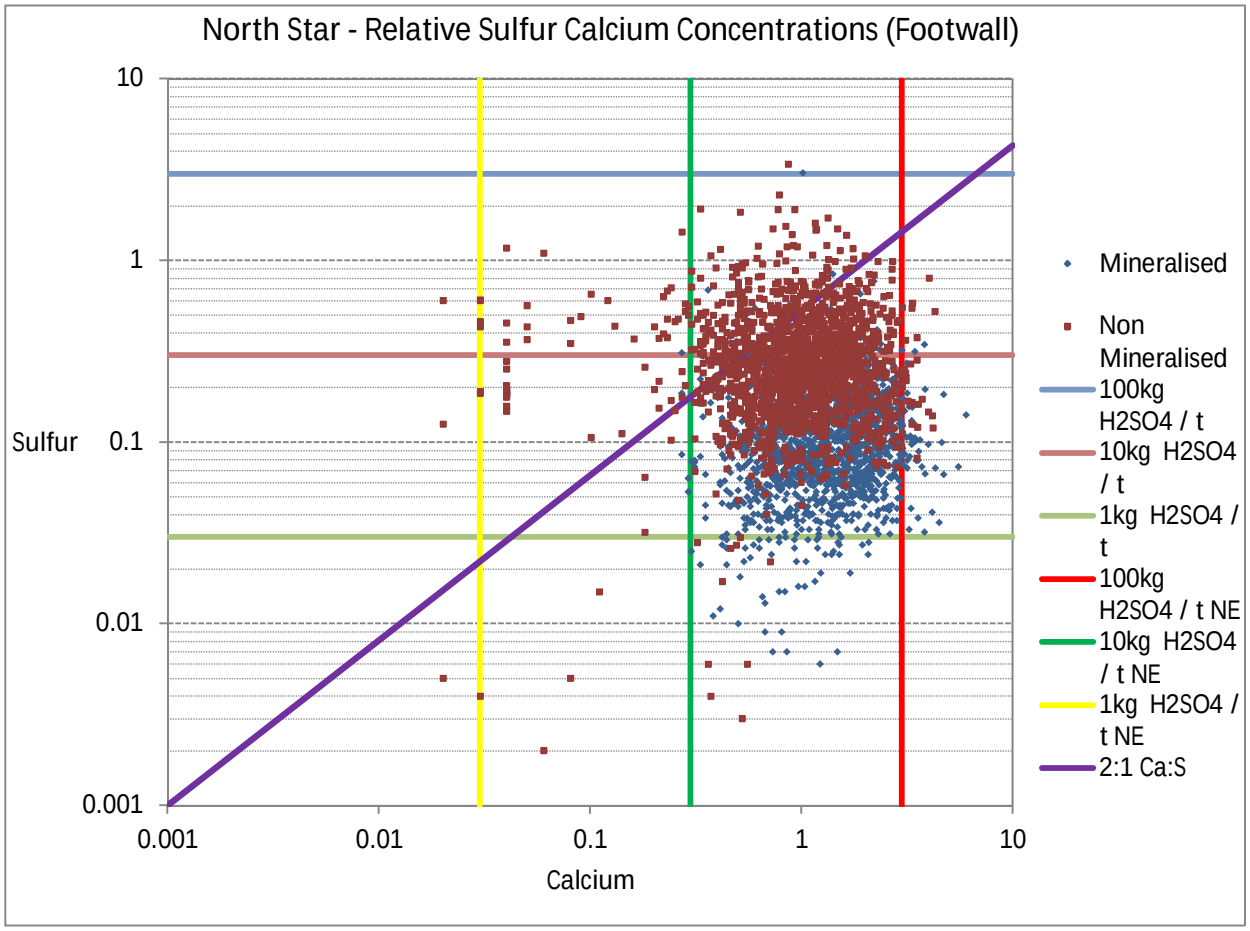

Figure 6 Relative sulfur: calcium concentrations (Footwall)

The assay database provided for the Hanging Wall material (Figure 7) indicated both mineralised and non-mineralised material to be present. Based on the sulfur: calcium ratio, the majority of this material is likely to be NAF, and may be NAC. A small proportion of the Hanging Wall material plots above the 2:1 Ca: total S line, and is therefore likely to be classified as PAF.

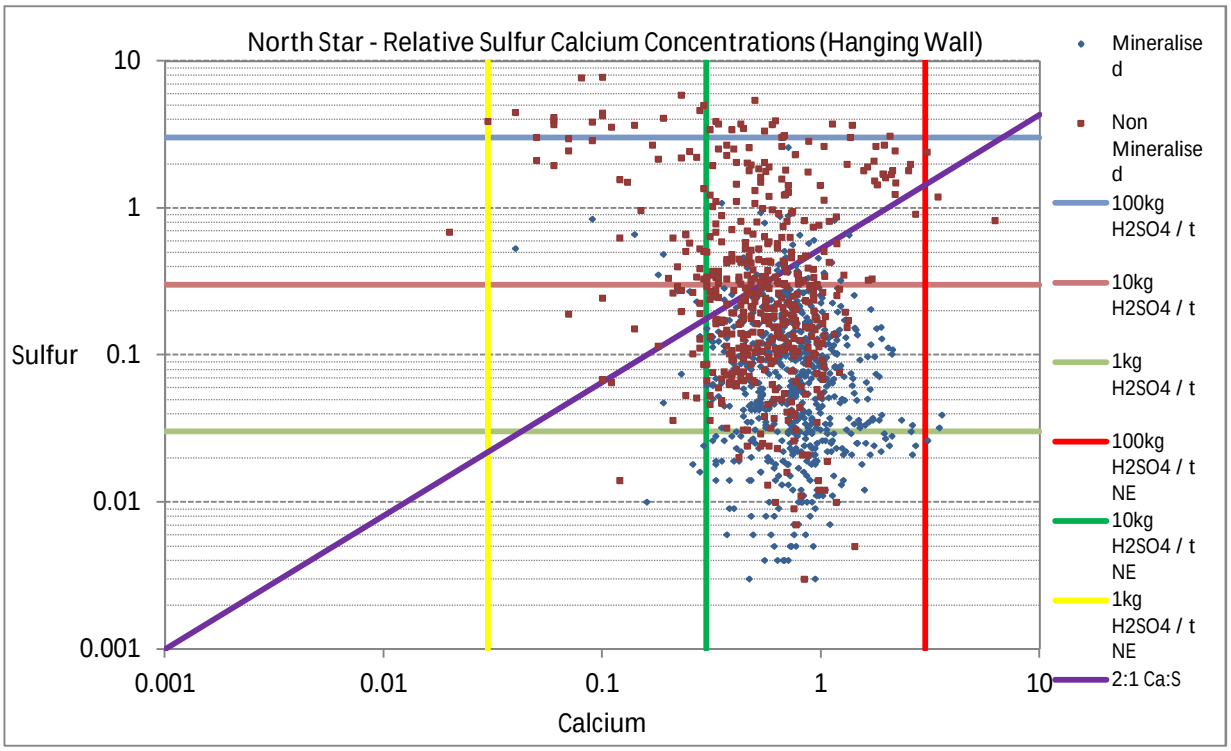

Figure 7 Relative sulfur: calcium concentrations (Hanging Wall)

The assay database provided for the BIF-North, BIF-South and Oxide materials, as well as the material which was unclassified (Figures 8 – 11) indicated both mineralised and non-mineralised material to be present. Based on the sulfur: calcium ratio, the majority of these materials are likely to be NAF, and may be NAC. A small proportion of the BIF-North and Oxide materials plot above the 2:1 Ca: total S line, and are therefore likely to be classified as PAF.

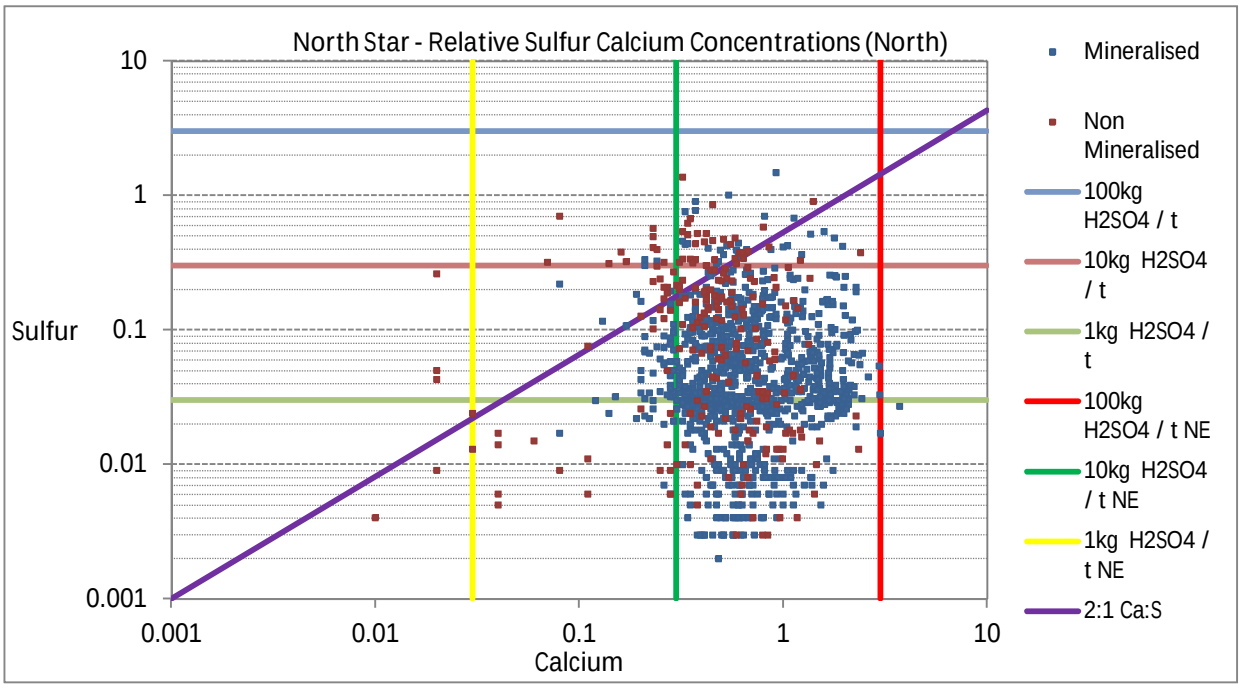

Figure 8 Relative sulfur: calcium concentrations (North)

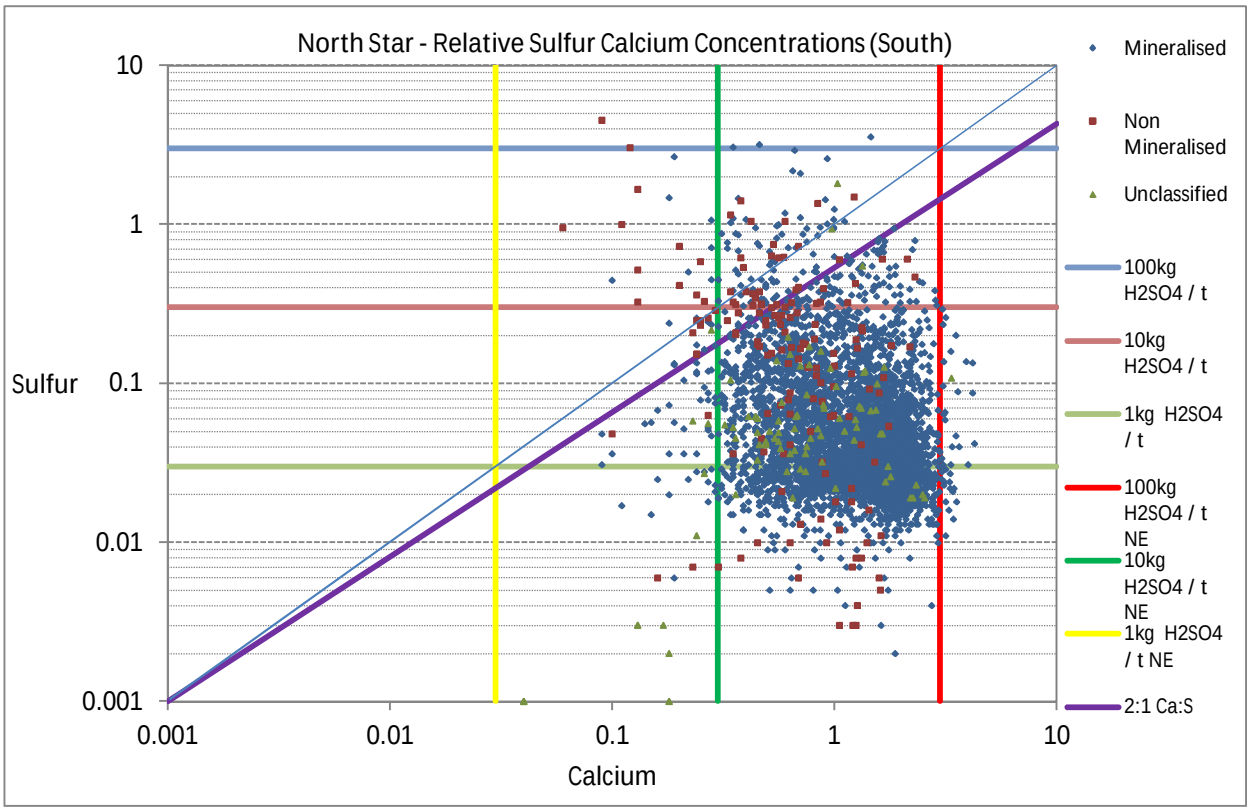

Figure 9 Relative sulfur: calcium concentrations (South)

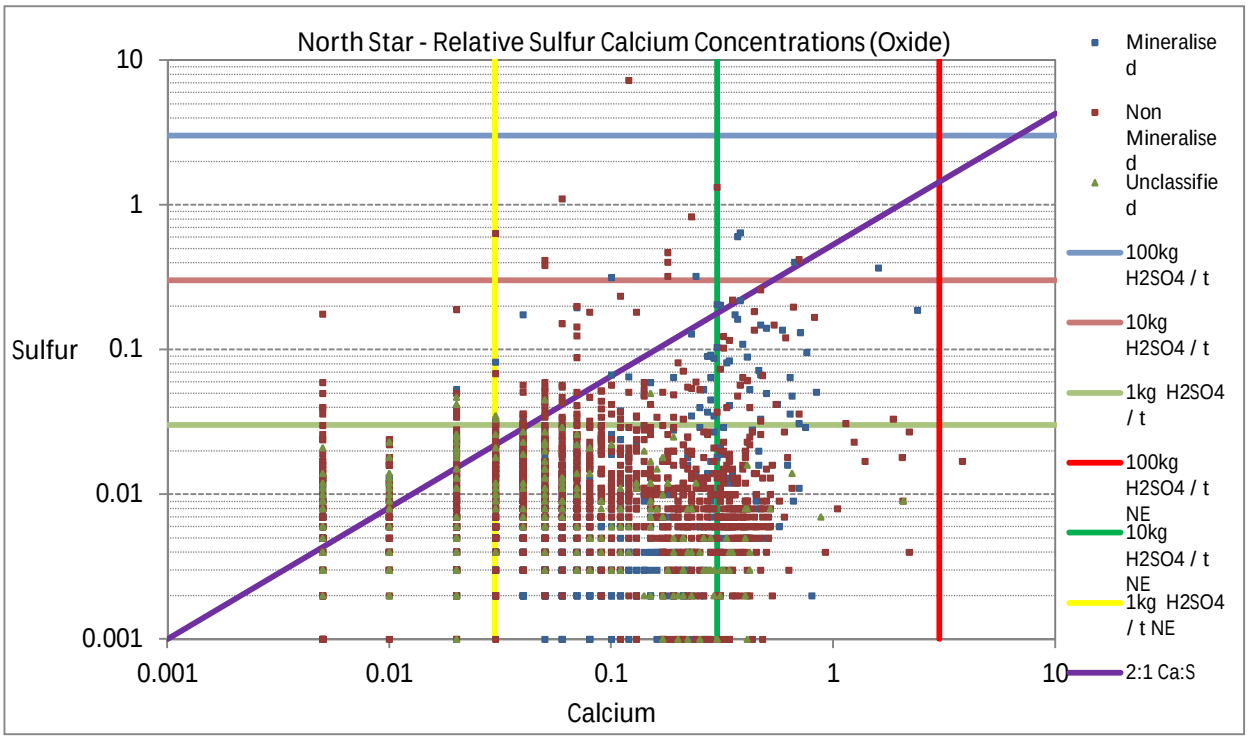

Figure 10 Relative sulfur: calcium concentrations (Oxide)

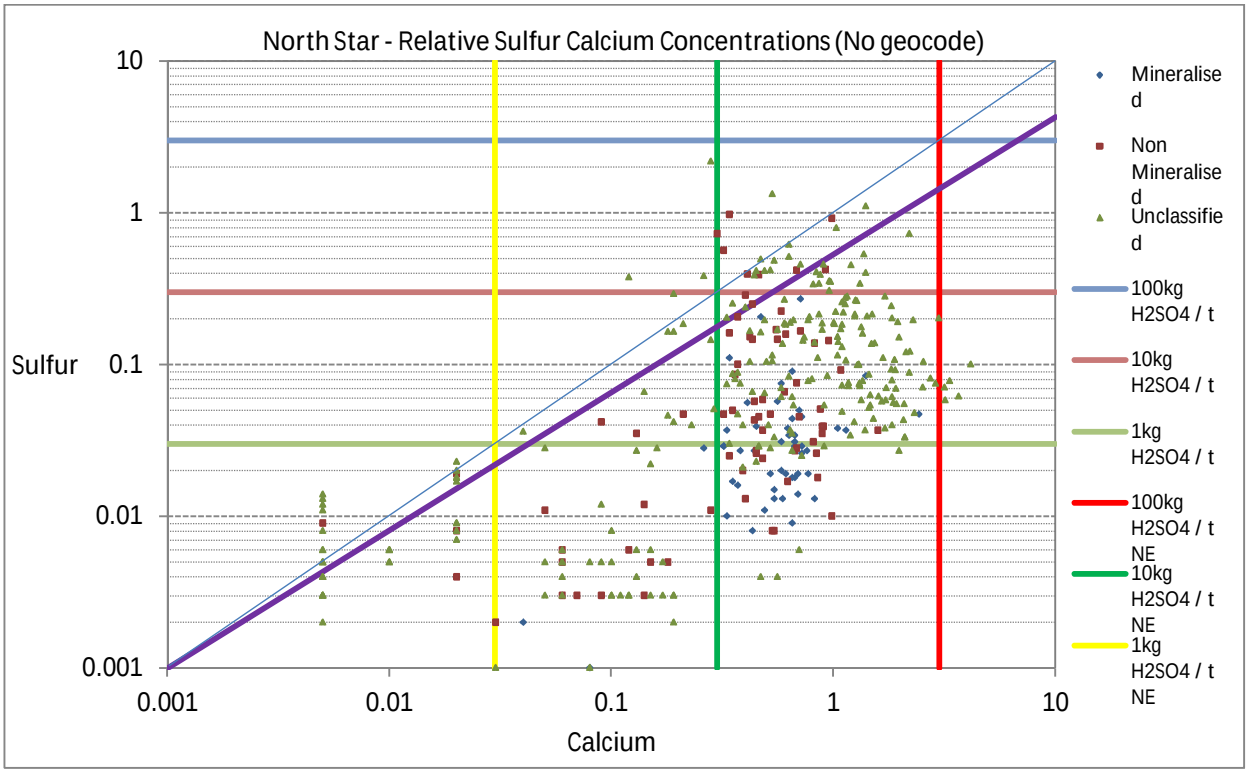

Figure 11 Relative sulfur: calcium concentrations (No geocode)

This data may also be represented by plotting ANC against MPA to determine the relative ratio of potential acid forming capacity to acid consuming capacity. In the results shown in Figure 12, the black

line indicates where ANC equals MPA (i.e. a ratio of 1:1), and the blue line indicates a ratio of ANC to MPA of 2:1. Samples plotting above the black line generally do not have sufficient relative neutralising capacity and therefore have the potential to generate acid drainage. Samples that plot between the 2:1 and 1:1 ratio lines are likely to present a low risk of acid generation (although the relative risk depends on the relative availability of the acid generating and neutralising capacity). Samples plotting below the blue line, with an ANC to MPA ratio of greater than 2:1, are unlikely to generate acidity (even allowing for some neutralising inefficiency due to sulfate coating of carbonate grains) given the excess neutralising capacity present.

The results presented in Figure 12 indicate that the majority of samples have ANC: MPA ratios of greater than two. These results indicate excess potential acid neutralising capacity relative to acid generating capacity is present within the majority of samples. However, a number of samples (mainly Hanging Wall and Footwall materials) plot between the 2:1 and 1:1 ratio lines and above the 1:1 ratio line, indicating the potential to generate acidity.

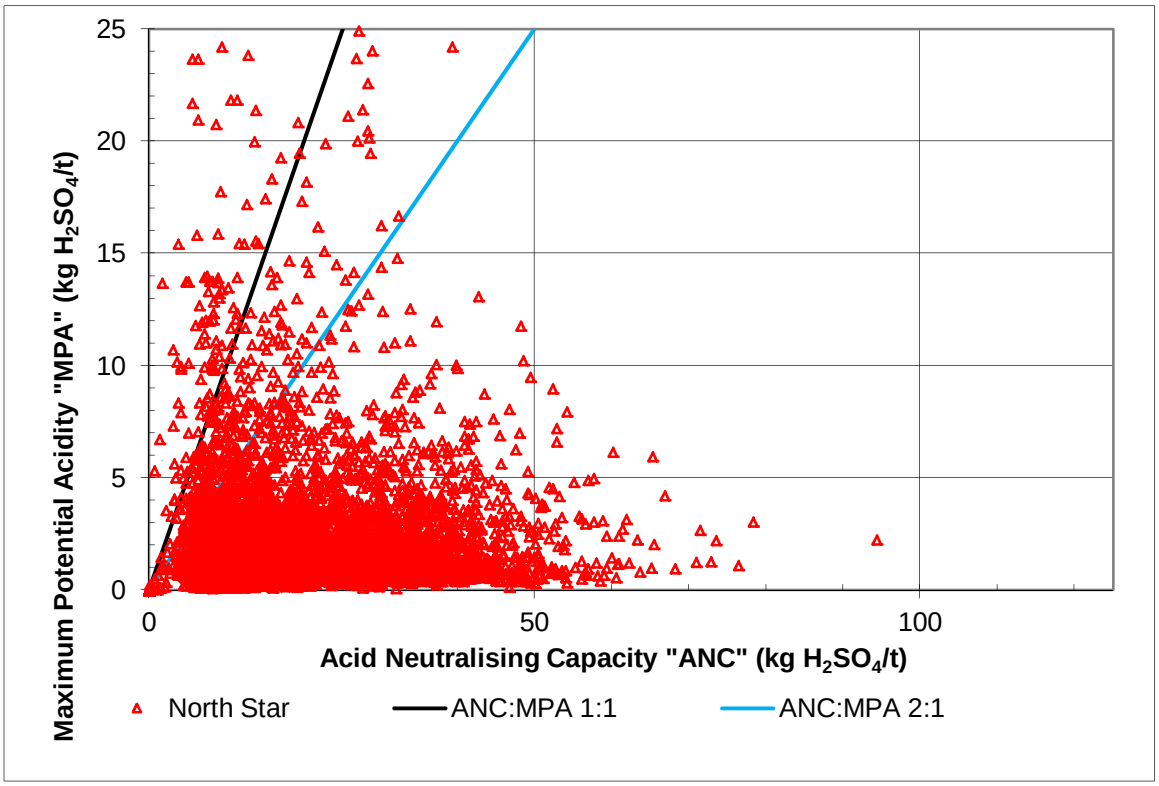

Figure 12 ANC/MPA ratios

6.6 Sulfur: Iron Correlations

The relationship between sulfur concentrations and iron grade, in addition to sulfur concentrations and calcium concentrations was assessed to determine the mineralogical relationship between these parameters. From the relationship the following observations are made:

- In general, sulfur and iron grade are inversely proportional; that is to say, non-mineralised (i.e. waste materials) units have higher sulfur grades than mineralised (ore) units (Figure 13); and
- The inverse relationship is pronounced in the non BIF units (Hanging Wall and Footwall). However, the relationship is less obvious in the BIF units (North and South). No relationship is observed in the Oxide material (Figures 13-14).

The implication of the relationships noted above is that waste rock and ore (and therefore tailings) are not likely to have very similar geochemical characteristics with respect to acid generating potential. In general, the mineralised lithologies (BIF) are more likely to be characterised as NAF, whereas PAF materials are more likely to occur within the non-mineralised materials (Hanging Wall and Footwall).

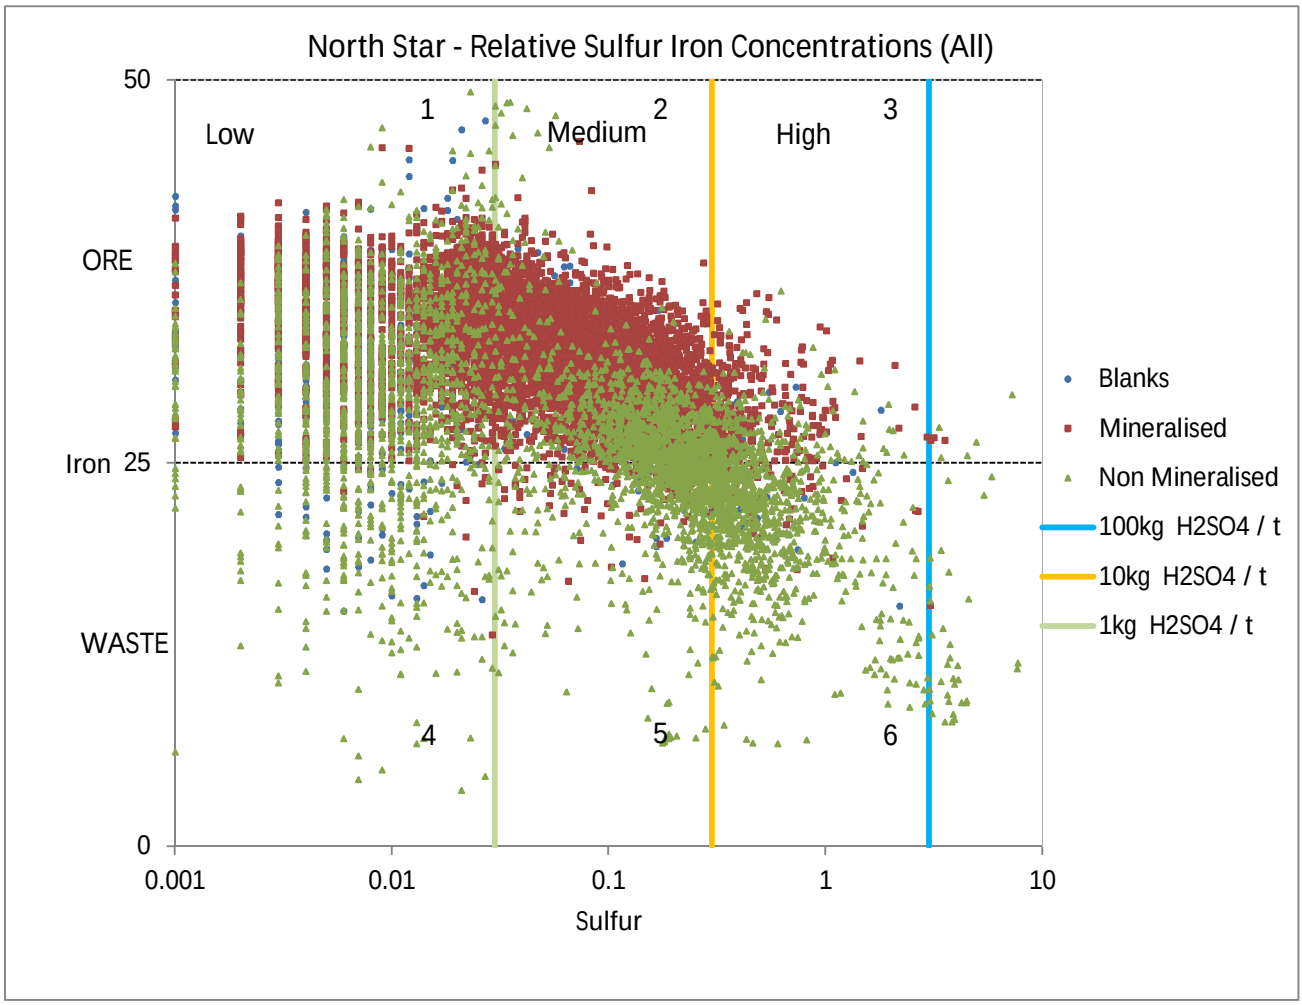

Figure 13 Relative sulfur: iron concentrations (all strata)

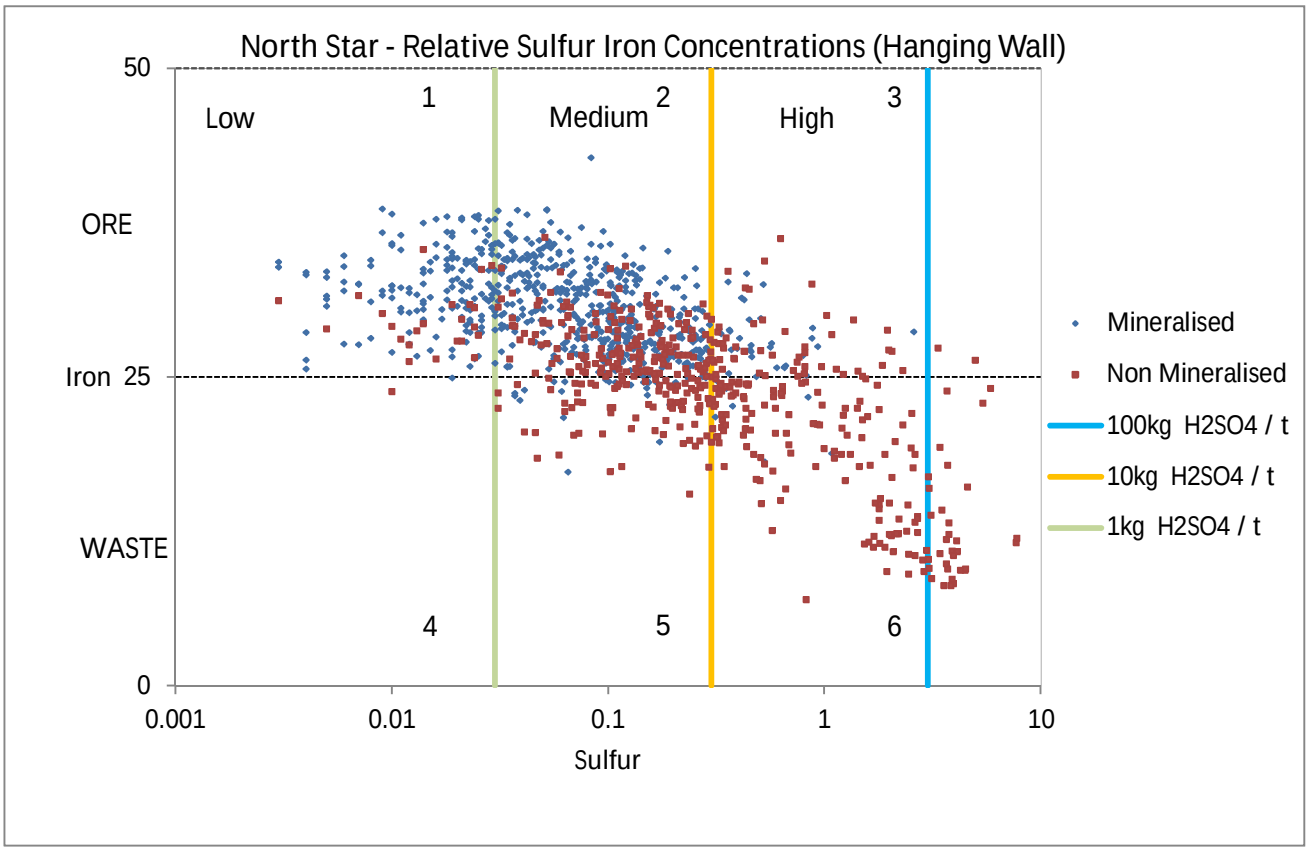

Figure 14 Relative sulfur: calcium concentrations (Hanging Wall)

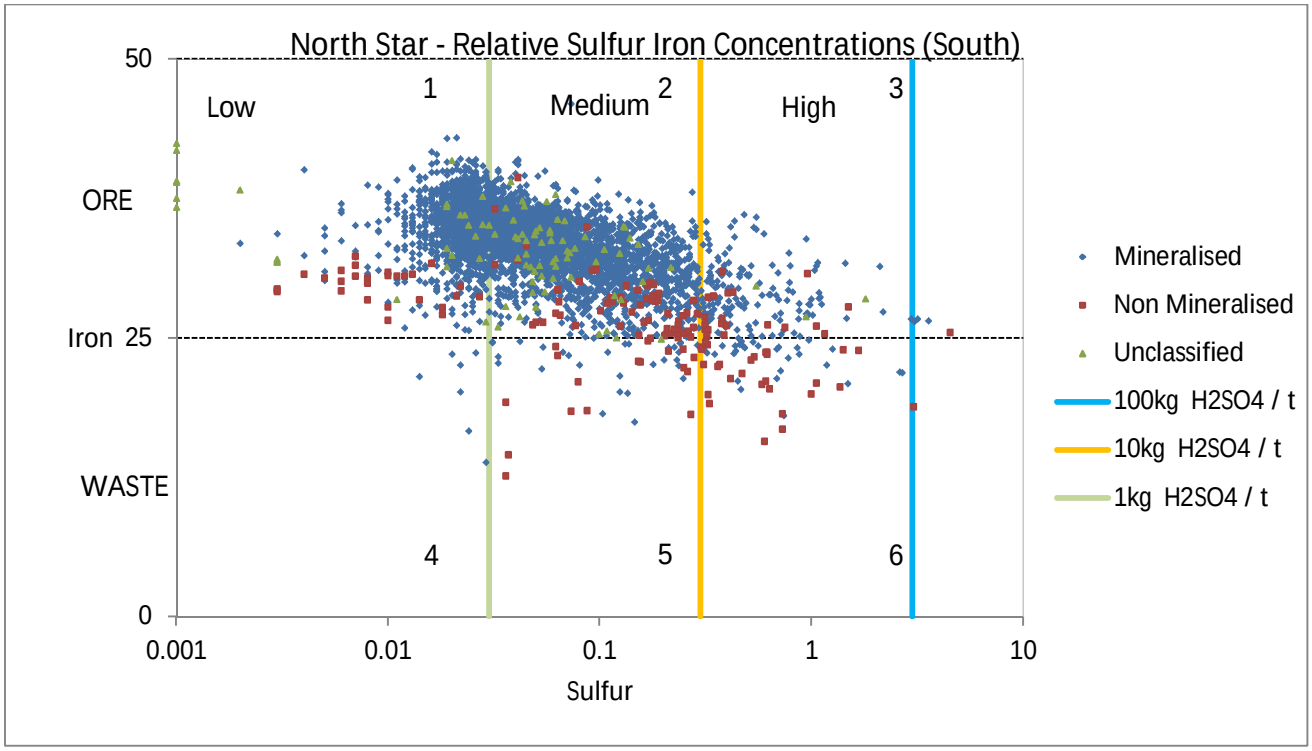

Figure 15 Relative sulfur: iron concentrations (BIF-South)

6.7 Summary high level assessment

A summary of all classification data is given as follows in Table 10:

Table 10 NAPP Classification

Lithological type	AMD classification		
Oxide (assumed ore/waste unit)	PAF:	0.44%	Samples: 10
	UC:	15.10%	Samples: 340
	NAF:	84.41%	Samples: 1900
	NAC:	0.04%	Samples: 1
South (assumed ore unit)	PAF:	1.57%	Samples: 65
	UC:	2.41%	Samples: 100
	NAF:	95.2%	Samples: 3949
	NAC:	0.82%	Samples: 34
North (assumed ore unit)	PAF:	1.19%	Samples: 14
	UC:	7.40%	Samples: 87
	NAF:	91.23%	Samples: 1072
	NAC:	0.17%	Samples: 2

Hanging Wall (assumed waste unit)	PAF:	10.59%	Samples: 100
	UC:	9.22%	Samples: 87
	NAF:	79.77%	Samples: 753
	NAC:	0.42%	Samples: 4
Footwall (assumed waste unit)	PAF:	2.86%	Samples: 82
	UC:	7.8%	Samples: 224
	NAF:	87.63%	Samples: 2515
	NAC:	1.71%	Samples: 49

Based on analysis by geological unit, assay database, and statistical analysis of the geochemical data set, PAF materials were identified predominantly in:

- The Hanging Wall: 12% PAF (HC), 10% UC; and
- The Footwall: 3% PAF (HC), 8% UC.

Although a low percentage of PAF material was identified in the BIF-South, this material comprises a very large component of the overall volume of the deposit and therefore may contain appreciable volumes of PAF materials.

It should be noted that although the Oxide contained a relatively high proportion of UC material of 15%, the majority of this material had a NAPP value of between 0-1kg H_2SO_4/t. The reason for this low level positive NAPP values is primarily due to low calcium values in the unit rather than elevated sulfur values. As a result, the Oxide is not considered to be at a high risk of containing PAF material.

Based on lithological specific analysis, detailed geochemical testing, and statistical analysis of the geochemical data set it appears that:

- The BIF material is considered to be NAF, however a small proportion of high PAF material has been identified in the BIF-South (1.6%) and the BIF-North (1.2%) material, based on a NAPP cut off of >10kg H_2SO_4/t.
- The majority of the Hanging Wall material is NAF. However, there is a significant PAF component with approximately 10% of material classified as PAF based on estimated NAPP values. A significant UC component has been identified with 9% of material classifying as UC based on estimated NAPP values.
- The majority of the Footwall material is NAF, however there is a PAF component with 2.9% of material classified as PAF. A significant UC component of 7.8% has been identified.
- The majority of the Oxide is NAF, however there is a significant UC component with 15% of samples classifying as UC. Laboratory testing indicates this material is likely to be NAF (see Section 8). It is likely that much of the material as fallen into the UC classification because of the low average NAPP value for this material (i.e. low calcium concentrations). It is therefore a lack of buffering capacity rather than elevated sulfur that results in the UC classification.
- With respect to tailings materials, some of the BIF-South material may be acid consuming. Approximately 20% of the material has a NAPP vale of -30kg H_2SO_4/t or lower.

The waste material has been classified based on the above analytical data as presented in Table 11.

Table 11 Preliminary Waste Material Classifications

Lithology type	PAF/NAF classification	Significant Sub classification (minor if any >1%, major if >10%)
BIF-South	NAF	Minor (1.6%) PAF Minor (2.4% UC)
BIF-North	NAF	Minor (3.9%) NAC Minor (1.2%) PAF
Hanging Wall	NAF/PAF	Major (11%) PAF Minor (9%) UC
Footwall	NAF/PAF	Minor (2.8%) PAF Minor (7.8%) UC
Oxide	NAF	Major (15%) UC
Waste stream	PAF/NAF classification	Significant Sub classification (if any)
Tailings (dry)	NAF/NAC	Minor (1.6%) UC Major (19.4%) NAC
Tailings (wet)	NAF/NAC	Minor (1.6%) UC Major (19.4%) NAC
Waste rock	NAF/PAF	Minor (4.2%) PAF Major (13%) UC

7. Drilling Data and 3D Geochemical Model Interrogation

7.1 3D Modelling in Encom Discover

3D modelling is a method for interpreting dispersed values defined in 3 dimensions into an estimate of every value in a defined volume.

The Encom Discover 3D software suite utilises discrete sample data and interpolation methods to derive estimated values for a defined volume of space. The volume is partitioned into a continuous array of smaller cells, each with a set X, Y and Z dimensions and one or more derived values based on geo-statistical methods of assessment of the discrete source data. The interpolation methods are similar to 2 dimensional geo-statistical methods and include deterministic methods (e.g. Inverse Distance Weighting) and probabilistic methods (e.g. Kriging).

7.2 Application of 3D Modelling for Geochemical Assessment

GHD has utilised Encom Discover 3D for this project in the following manner:

- All assay data and drill hole data available from exploration drilling in the project area was imported into the model;
- NAPP values were calculated for all assay data points (based on total sulfur and calcium assay data values);
- Classification criteria for the geochemical block model are provided in Table 8, Section 6.4, that summarise model classes, being: PAF, NAF, NAC and UC;
- Geological classification has been applied in the model directly from the Fortescue drill hole database; and
- The current life of mine pit shell has been imported into the model to allow assessment of data within the pit shell.

The model has been clipped to areas where exploration drilling has been carried out. Some areas within the pit shell have very low densities of drilling and cannot be modelled accurately and have therefore been excluded from modelling. The clipping carried out is shown in Appendix D.

Two separate models have been set up GHD in an effort to rationalise the fact that drilling data is not available for approximately 40% of the pit shell volume:

- Model 1: Clipping the model to the extent of the drill data and not extrapolating into the rest of the pit shell where there is no data; and
- Model 2: Clipping the model to the pit shell, and extrapolating results between holes lying within the pit shell.

It should be noted that modelled volumes/proportions for the geochemical classes may differ slightly to the statistical results given for the analysis in the high level review as the model is effectively generating data in areas where there is little information (i.e. extrapolation between drill hole locations).

The total model volumes were determined as follows:

- Model 1: 501,035,000m^3
- Model 2: 797,206,250m^3

The significantly lower total volume for Model 1 relates to the fact that drilling does not extend into the western area of the pit shell. The “extrapolated” portion of Model 2 is therefore calculated as the difference between the two models which is 296,171,250m^3 (40%).

7.3 Gridding Method Overview

7.3.1 Discretised Gridding

The discretised gridding method uses inverse distance weighting (IDW) rules to interpret and place each cell into one of the possible classes, depending upon:

- The established rules; and
- The net distance of each sample from each cell.

Discretised gridding effectively treats all inputs as classes and not as numbers, so that each cell gets the ‘most likely’ option – and not an average value. This method is utilised for assessment of materials with ‘classes’, such as geological units.

IDW therefore uses measured values (in this case, classes) surrounding the cell to determine the class of the cell where the measured values closest to the cell have a greater influence on the determination than values which are further away (i.e. a weighting is applied which decreases with distance from the cell).

7.3.2 Grid Size

The grid size defines the volume of area that will have the estimated class. The grid size used herein is defined in Section 7.3.5.

7.3.3 Search Parameters

Search parameters define the rules used to determine whether a sample value falls within the zone of influence for any particular cell. Rules include search distance and bearings, as well as the possibility of setting required search sectors and the option for expanding search zones if no samples are found in the initially defined zone. Elliptical (anisotropic) search radii can also be defined. This is used where the feature being modelled has an identifiable non equal relationship in space.

7.3.4 Gridding Parameters

Gridding parameters define the relative weighting given to samples based on their distance away from the calculated cell. The weights applied are proportional to the inverse of the distance between the cell and the measured value (class). The default is a power of 2 (weight = 1/Distance^2). Other weighting options not used herein can include linear, exponential and Gaussian.

Two other options will alter the gridding results in a significant way:

- The exact hit distance defines the distance out from any source sample where a grid cell will be given the source sample value instead of an interpolated result; and the elliptical weighting option

allows elliptical search parameter to influence the weighting. This can make a significant difference in the calculations if selected, as samples on the long axis will get weighted the same as much closer equivalent samples on the short axis.

7.3.5 Specific Model Parameters

The following parameters for 3D modelling were used as part of the assessment:

Mineralised Geology Model

- Method: discretised gridding;
- Grid Size:
    - Cell Width (m) : 25, Cell Length : 25, Cell Height : 5;
    - Model Coordinate (maxX, maxY, maxZ): (713840, 7651780, 500);
    - Model Coordinate (minX, minY, minZ): (709040, 7646880, -200);
    - Model size: 192 columns, 196 rows, 140 planes; and
    - Model size: 4800m Width, 4900m Length, 705m Height.
- Search parameters:
    - Elliptical Search 100m in x/y dimensions; and
    - 50m in z dimension. 3 search expansions (to a max of 600/300m) when insufficient sample points are found in initial search radius.
- A maximum of 16 samples and a minimum of 1 are required for successful calculation of a grid cell;
- Gridding parameters: discretised parameter classes: all lithology classes; and
- Weighting option: Power = 2;
    - The outputted Voxel grid was then clipped to the topographical surface (above) and the pit outline (below).

NAPP Model

- Method: Krig gridding;
- Grid Size:
    - Cell Width (m) : 25, Cell Length : 25, Cell Height : 2;
    - Model Coordinate (maxX, maxY, maxZ): (713840, 7651780, 480);
    - Model Coordinate (minX, minY, minZ): (709040, 7646880, -80);
    - Model size: 192 columns, 196 rows, 280 planes;
    - Model size: 4800 Width, 4900 Length, 560 Height.
- Search parameters:

- Elliptical Search 100m in x/y dimensions; 16m in z dimension. 3 search expansions (to a max of 600/48m) when insufficient sample points are found in initial search radius. Bearing 260 degrees, Inclination 80 degrees.

- A maximum of 16 samples and a minimum of 1 are required for successful calculation of a grid cell;
- Method:
  - Estimation - Point estimation; and
  - Method – Ordinary kriging.
- Variogram parameters; and
  - Isotropic Nugget: 1.4248; and
  - Nest type: Spherical; Nugget = 0; Positive Variance = 74.77; Primary Range = 10.344; Minor Range = 10.344; Depth Range = 10.344; Strike = 100; Plunge = -85, Dip = 0.
- The outputted Voxel grid was then clipped to the topographical surface (above) and the pit outline (below).

Interrogation of the drill hole database has been carried out by modelling using the Discover 3D add on package for MapInfo. The North Star Project borehole data that was analysed as part of this assessment is included in Appendix D.

7.4 Classification of Materials

For any additional geochemical testing to be undertaken, classification of the materials will follow the criteria set out in Table 8, Section 6.4.

When samples are classified as uncertain (UC), additional static and kinetic tests should be used to determine if the material is likely to pose an AMD risk.

A plan view of the 3D model data is provided in Appendix D. On this plan, maximum NAPP values in any one location (i.e. the highest results at any depth at each location) are shown using a colour coded key.

7.4.1 Modelled Waste/Ore Volumes by Classification

The Discover 3D model was used to determine volumes of waste and ore by classification. The classification system used was as outlined in Table 8, Section 6.4.

Units classified as mineralised in the assay database are assumed to be potential ore, while units classified as non-mineralised are assumed to be potential waste materials. Given that the geological model is currently being updated to include a revised resource estimation, unit classification as waste or ore for the purposes of this geochemical assessment will be dynamic over time. The relative model volumes provided herein should therefore be viewed as conceptual in nature.

7.5 Model 1 Results

The results for Model 1 are given in Table 12, and summarised as follows:

- The majority of materials are NAF with 86% (428,873,750 m3) of the model volume falling under this category;

- Total calculated PAF is 26,592,500 m^3 (5.3%), with the majority of this (22,261,250 m^3) being found within the Hanging Wall material;
- The proportion of Hanging Wall material that the model classifies as PAF is 24% (22,261,250 m^3);
- Total calculated UC material is 25,643,125 m^3 (5.1%), with the Hanging Wall containing the largest relative proportion of this material (10,001,250 m^3); and
- Total NAC calculated is 19,925,625 m^3 (4%), with the majority of this (12,608,125 m^3) being found in the mineralised portion of the BIF-South.

Table 12 Model 1 Results (Volumes in m^3)

Geology	Mineralised class	NAC	NAF	PAF	UC	Total
Oxide	non-mineralised	258,750	62,639,375	1,800,000	5,627,500	70,325,625
Oxide	mineralised	120,000	16,421,875	832,500	1,087,500	18,461,875
North	non-mineralised	8,750	5,571,250	8,750	494,375	6,083,125
North	mineralised	325,625	69,360,000	543,750	2,818,125	73,047,500
Footwall	non-mineralised	1,967,500	48,500,000	510,625	3,025,625	54,003,750
Footwall	mineralised	4,051,250	48,141,875	44,375	831,250	53,068,750
Hanging Wall	non-mineralised	141,250	20,132,500	14,052,500	5,970,000	40,296,250
Hanging Wall	mineralised	387,500	38,554,375	8,208,750	4,031,250	51,181,875
South	mineralised	12,608,125	116,911,875	30,625	175,000	129,725,625
South	non-mineralised	56,875	2,640,625	560,625	1,582,500	4,840,625
	Total	19,925,625	428,873,750	26,592,500	25,643,125	501,035,000

7.6 Model 2 Results

Model 2 was run to extrapolate into the area of the pit shell where Model 1 did not assess (40% of total volume). Results are given as follows in Table 13:

Table 13 Model 2 Results (Volumes in m^3)

Geology	Mineralised	NAC	NAF	UC	PAF	Total
Oxide	non-mineralised	2,258,750	125,521,250	7,959,375	2,625,625	138,365,000

Geology	Mineralised	NAC	NAF	UC	PAF	Total
Oxide	mineralised	120,000	16,992,500	1,115,000	281,250	18,508,750
North	non-mineralised	2,500	6,536,875	648,750	8,750	7,196,875
North	mineralised	759,375	97,729,375	3,542,500	1,104,375	103,135,625
Footwall	non-mineralised	2,504,375	78,849,375	3,956,875	833,125	86,143,750
Footwall	mineralised	4,210,000	61,970,000	1,217,500	66,250	67,463,750
Hanging Wall	non-mineralised	179,375	39,943,750	15,030,625	21,864,375	77,018,125
Hanging Wall	mineralised	515,000	72,030,000	15,436,250	19,784,375	107,765,625
South	mineralised	17,008,750	168,047,500	2,521,250	1,033,750	188,611,250
South	non-mineralised	60,625	2,727,500	178,750	30,625	2,997,500
	Total	27,618,750	670,348,125	51,606,875	47,632,500	797,206,250

The following points are relevant when considering the results of Model 2:

- Due to the limited depth of drilling relative to the total depth of the pit shell, the model has extrapolated the classification of BIF as mineralised/non-mineralised to the depth of the pit shell. This has resulted in a large volume of the BIF-North and BIF-South being classified as non-mineralised (as a result of extrapolation of results from the base of the drill holes). GHD understands that a key assumption of the pit shell being extended to depth below the base of the drilling is that the mineralised nature of the BIF extends vertically. As a result it is likely that the material classified as non-mineralised is more likely to be classified as mineralised if the pit shell is to extend to the projected depth;
- As result of the extrapolation of data by the model, some Oxide material has been classified as PAF in the west of the deposit. This is a result of the model extrapolating the occurrence of high sulfur material to surface based on the mineralisation following the sub vertical dip of the geology. Given the low levels of sulfur noted in the Oxide from testing to date, this assumption is not likely to be realistic as the Oxide material represents a zone of oxidised material which has been depleted in reactive sulfides;
- In general, Model 2 results are in agreement with Model 1 results, although the extrapolation of data at depth into the BIF and in the west into the Hanging Wall/Oxide has resulted in significant volumes of PAF being estimated within the Hanging Wall and Oxide. Although potentially conservative, these projections allow consideration of the potential for PAF materials to occur in the areas of the pit for which there is no drilling data;
- The majority of materials are NAF with 84% (670,348,125 m^3) of the model volume falling under this category;
- Total calculated PAF is 47,632,500 m^3 (6%), with the majority of this (41,648,750 m^3) being found within the Hanging Wall material;

- The proportion of Hanging Wall material that the model classifies as PAF is 23% (41,648,750 m^3);
- Total calculated UC material is 51,606,875 m^3 (6.5%), with the Hanging Wall containing the largest relative proportion of this material (30,466,875 m^3); and
- Total calculated NAC is 27,618,750 m^3 (3.5%), with the majority of this (17,069,375 m^3) being found in the mineralised portion of the BIF-South.

7.6.1 General Conclusions from Modelling

The following conclusions are drawn from the modelling:

- The Hanging Wall contains a high proportion of PAF material. With respect to overall volumes of PAF calculated by the model within the model space, the majority of PAF is found within this lithology type;
- The BIF does not appear to contain significant volumes of PAF by overall proportion, although it is noted that PAF material has been modelled to occur within this lithology type. Although PAF has been identified as a significant proportion of the BIF, it has been identified as NAC. The presence of the NAC material on a ratio of approximately 10:1 with respect to PAF material is relevant when considering that the overall classification for the BIF unit is likely to be NAF;
- The Oxide contains appreciable levels of PAF and UC. The presence of this volume of PAF is not expected from the Task 1 review which indicates the Oxide as having low sulfur levels. The modelled PAF volumes are considered to be an artefact of the nature of the model extrapolation of data. The model is extrapolating the presence of sulfidic material based on sub vertical dipping geology. Where there is limited drilling data at the surface (which occurs in the west of the model due to the boreholes being inclined to the west) the model has extrapolated the presence of sulfidic material from depth and projected to surface;
- A significant volume of material (47,632,500 m^3) has been identified as UC. Although low risk with respect to AMD as a result of NAPP values being lower than 10kg H_2SO_4/t, detailed testing is required to confirm if this material is likely to be NAF or PAF; and
- The total volume of PAF estimated by Model 2 is approximately 47,632,500 m^3. The majority of this is found within the Hanging Wall material. The eventual waste stream these materials report to (i.e. tailings or waste rock) will depend on the eventual classification of these materials as waste or ore within the mine model. The volumes of PAF projected to report to the waste rock dump and tailings stream should be revised once the resource model has been completed. Further drilling in the west of the deposit will allow the model to be refined to allow more accurate classifications of PAF materials in the Hanging Wall material.

7.7 Cross Sections

Cross sections through the pit area as produced by the model are provided in Appendix C. The cross-sections show the following data:

- The pit shell outline;
- The down hole logged geology;
- Mineralisation class (i.e. mineralised, non-mineralised);
- Geochemical class (NAPP model class); and

- NAPP provided as bar lines. Where positive results are recorded bars run to the right, where negative values are recorded bars run to the left.

Sections through the 3D geochemical model created by GHD (using Discover 3D) are given in Appendix D. These sections were reviewed to gain an understanding of the general distribution of sulfur containing material relative to the ore and waste materials, and to identify material types that may require further detailed AMD testing. The cross sections show the following:

- The majority of the materials classified as PAF occur within the Hanging Wall and at a depth of greater than 150m. Large blocks of PAF have been generated by the model within the Hanging Wall as a result of the vertical continuity of the occurrence of high sulfur material shown in the down hole NAPP data below this depth. It is important to note that limited drilling data in the western zone of the deposit means that the true extent of the PAF material is unknown. The model has been set up to follow the strike and dip of the prevailing geology, hence the extrapolation of material as PAF has been determined by assumption that the PAF material occurs as continuous blocks of material orientated north south with a sub vertical dip;
- Limited areas of correlated blocks of PAF are noted in the Oxide. The model orientation has also resulted in material being reported as PAF within Oxide material in the west of the pit shell where there is currently no drilling data. Based on geochemical data analysed to date by GHD, it is not expected that PAF material will be found in the Oxide material. As a result, the PAF estimates given by the model for the Oxide are likely to be overestimates;
- Limited drilling data in the western area has resulted in the model generating a significant amount of extrapolated data. Further drilling is required to determine the nature of the geochemistry of the material in this area, however, at this time the model extrapolation is considered as a reasonable conservative assumption of the likely geochemical characteristics of material in this area;
- Due to the thinly bedded nature of the BIF material, the relatively coarse drill spacing of exploration drilling and the variable depth of the oxide, there remains the possibility that additional PAF material may be encountered during mining activities. The source of PAF material in the BIF appears to be thin and discontinuous bands of pyrite which are likely to be highly localised in extent.
- Isolated blocks of PAF material are noted within the BIF, in particular the BIF-South unit. Large blocks of PAF are not generated by the model as a result of the isolated and spatially discontinuous nature of the high sulfur material in the BIF;
- Zones of material classified as NAC are evident in the BIF, however large blocks have not been generated by the model which indicates that the NAC material is spread diffusely and does not have a spatial relationship; and
- Blocks of PAF are evident in the Footwall material, although they not as continuous or as spatially correlated as the blocks in the Hanging Wall. Limited drilling data to the east of the deposit means that the model has extrapolated into these areas, the true nature of the distribution of PAF material requires further drilling to be carried out.
- Drilling data within the deposit comprises drill lines with a 250m north-south spacing, but a denser spacing along the east-west drill lines. This drill spacing was determined to assess the *in situ* geology which has a north-south strike and sub vertical dip to the west. The rationale being that there is likely to be higher mineralogical variability across strike given that the BIF comprises thinly bedded materials than along strike. As a result of the drill spacing, the model has extrapolated data into the

250m block between drill lines. Therefore, additional drilling is required to further determine the detailed nature of the *in situ* geochemistry However, for the purposes of this assessment, the model extrapolation is considered to be an appropriate conservative assumption of the likely geochemical characteristics of units within these areas. Any additional resource definition drilling carried out on site will refine the accuracy of the model.

8. Additional Geochemical Test-Work Programme

8.1 Selection of Archived Samples for Further Testing

A sampling plan consisting of samples selected from Fortescue archived core, drill cutting samples, and pulped samples (that were subject to previous assay) was completed for additional static and kinetic geochemical characterisation tests [2]. Results from the additional testing has been used to:

- Further define the geochemical properties within the different lithological units;
- Define the AMD risk;
- Assess the performance of the 3D model; and
- Allow for calibration of the 3D model.

The sampling plan was designed to provide good coverage according to a number of criteria, including depth and spatial extent.. The sampling plan had to include a representative selection of the different lithological units present and of both non-mineralised and mineralised samples. Material previously identified by assay test results as possessing high total sulfur concentrations was also targeted.

As noted above, geological material available from previous exploration drilling was identified as an appropriate sample source for the sampling programme. As this material was used for the original assay testing as well as being used to populate the 3D model, it was deemed appropriate for model calibration once the more detailed static and kinetic test data became available.

The process of identifying samples suitable for the geochemical characterisation programme started with identifying suitable boreholes. These were selected on an approximate 500m horizontal spacing in addition to using output from the 3D model, specifically targeting boreholes that had a high likelihood of intersecting zones of elevated total sulfur concentrations and lithologies of particular interest. For most boreholes, drill chips or core were only available for limited sections. Therefore, even depth representation was not possible in some instances for the purposes of geochemical characterisation.

Once drill holes were selected, samples were chosen down the profile. Depth intervals of either 10 or 20m were preferred to ensure a representative dataset across all lithological units. However, this was not always possible, as noted above. Finally, samples were targeted based on elevated total sulfur or calcium results relative to the mean value of the dataset to ensure material that was classified as PAF or NAC by the preliminary assessment could be assessed.

8.2 Detailed Testing Programme

The testing programme submitted to the laboratory to date included the following analysis (Table 14):

Table 14 Testing Programme

ANALYSIS	SAMPLES ANALYSED
Multi-elemental analysis by ICPMS	140^

[2] This included NAG, NAPP, paste pH, metals suite, NAG liquor, kinetic NAG, deionised water leach, weak acid leach, XRD, ABCC Curve, and Humidity Chamber.

Summary tables of results from the detailed geochemical test programme are provided in Appendix F, while the full laboratory results are provided in Appendix G. Results are discussed in the following sections.

8.3 NAPP/NAG Testing

NAG testing provides an indication of the net behaviour of rock when fully oxidised (AMIRA 2002). It is performed by rapidly oxidising the pulped rock sample with a hydrogen peroxide solution. It is a relatively aggressive reaction as this method is required to fully oxidise the sulfides and carbonates in the sample in a short period of time. From the resulting aliquot, the pH is measured, and the aliquot is then titrated to measure the acidity. The titration is to endpoints of pH 4.5, which is indicative of typical pyrite oxidation acidity, and pH 7.0 to assess remaining acidity from other oxidised minerals in addition to metals hydrolysis reactions.

Net Acid Producing Potential (NAPP) is determined by the summation of two acid base accounting parameters. The total sulfur content of the sample, usually measured with a LECO apparatus, is used to derive the maximum potential acidity (MPA), the theoretical maximum amount of sulfuric acid produced if all sulfur in the sample is oxidised. The acid neutralising capacity (ANC) is then calculated by titrating an unoxidised sample with acid to determine its ability to neutralise an acid solution. The NAPP is then derived by adding the negative ANC to the MPA (all expressed in kg H_2SO_4). A net positive value indicates that the sample may produce acid, while a net negative value indicates that the sample is either Non Acid Forming (NAF), or Net Acid Consuming (NAC), commensurate with the final value (Table 8, Section 6.4).

Due to the low risk with respect to PAF materials identified from the Task 1 analysis, the following strategy was adopted for detailed geochemical testing of materials:

- NAPP testing was carried out on only a limited number of samples (n=151 samples) on the assumption that NAPP could be accurately estimated from Task 1 NAPP geochemical data, and

because total sulfur concentrations were generally low for the majority of materials (>90% classified as NAF from Task 1 analysis); and

- NAG testing was carried out on a representative sample population (n=1,170 samples) that included all material types

To classify the acid forming potential of AMD material, the NAG pH is plotted against NAPP (Figure 16), to determine if the two tests confirm the sample is PAF, material is classified on the following basis:

- PAF: Positive NAPP and NAG pH less than 4.5),
- NAF (negative NAPP and NAG pH greater than 4.5),
- Contradictory/uncertain (UC).
- NAC: NAF material with a NAPP value of less than -50 H_2SO_4 is generally further sub-classified as net acid consuming material

The results from the testing are shown on the following figures:

- Figure 16: results for laboratory derived NAPP against NAG pH shown on a standard box plot;
- Figure 17: results for Tasks 2-3 laboratory derived NAPP against laboratory derived NAG pH shown on a standard box plot (Oxide and BIF-South);

8.3.1 Summary of Results

The following conclusions are drawn from Figures 16-22, with laboratory NAG pH results indicating that:

- 4 samples of BIF-South have a NAG pH value of <4.5 and are therefore likely to be PAF;
- 8 samples of Hanging Wall have a NAG pH value of <4.5 are therefore likely to be PAF; and
- All other samples tested had NAG pH values >4.5 indicating these materials are not likely to be PAF.

The results of the laboratory NAG test data has been plotted on a standard box plot against the estimated NAPP value from Test 1 analysis. The box plots indicate that the majority of the materials tested can be classified as NAF, based on the AMD classification of NAF material, as having a NAG pH of >4.5 and a NAPP value <0kg H_2SO_4/t. In summary the results show that:

- 99% of samples (n=1,151 samples) (BIF-North, BIF-South, Footwall, Hanging Wall and Oxide) tested had NAG pH values >4.5 indicating these materials are not likely to be PAF; and
- 1% of samples (n= 13 samples) tested had NAG pH values <4.5 indicating these materials are likely to be PAF.

Where laboratory NAPP testing (150 samples) was carried out, a comparison was made with the estimated NAPP from Task 1. The results have been plotted on a box plot (Figure 20). In general, the laboratory NAPP results are more negative than the estimated model NAPP values. This is perhaps to

be expected, as the laboratory NAPP test includes all calcium species both neutralising (calcite and dolomite), and non-neutralising (siderite). This indicates the estimated NAPP values in Task 1 testing are conservative (although on balance the tests are deemed to be appropriate for the purposes of this report).

For the 733 samples where both NAPP has been calculated within the Task 1 geochemical model and laboratory NAG testing results are available, good correlation generally exists between Task 1 NAPP classification and NAG pH results (Figure 19). The comparison indicates that:

- 26 samples were identified as PAF based on the estimated NAPP value of >10kg H_2SO_4/t, whereas 11 of these samples were confirmed as PAF based on laboratory NAG testing
- All samples identified as PAF from NAG pH values of <4.5 had corresponding estimated NAPP values of >15kg H_2SO_4/t.

The results of the NAG testing received to date provide strong agreement with the Task 1 provisional classifications based on the estimated NAPP values. It is noted that in 14 cases the estimated NAPP value classified material as PAF (based on a cut off for NAPP of >10kg H_2SO_4/t), when the lab NAG pH test data indicated the material to be UC or NAF. On this basis, it is considered that the estimated NAPP values in the geochemical database are likely to be conservative and are more likely to overestimate the volume of materials classified as PAF than underestimate.

The detailed NAG pH test results indicate that 35 samples returned NAG pH 7 values of >0kg H_2SO_4/t, indicating that the test resulted in the net generation of acidity. Related to the NAG pH values the results indicate:

- 13 samples (Hanging Wall and BIF-South) had NAG pH 7 values of >5kg H_2SO_4/t. These samples correlate with those identified as having NAG pH values of <4.5. Based on these results the materials are likely to be PAF; and
- 22 samples (comprising Oxide, Footwall, Hanging Wall and BIF-South materials) had slightly positive NAG pH 7 values of between 0-5kg H_2SO_4/t, with these same samples returning NAG pH values of between 4.5 and 7. These results indicate that although these materials produced acidity as a result of the NAG test, this occurred at very low levels and these materials have a very low potential to generate acidity.

A comparison between the NAG pH 4.5 and NAG pH 7 results has been carried out to determine the potential source of acidity within the samples, a graph of the two sets of data is given in Appendix E. Results indicate that:

- The majority of the total acidity released during testing of the samples that are likely to be PAF (which have NAG pH 7 values of >5kg H_2SO_4/t) (which includes samples of Hanging Wall and BIF-South) is related to oxidation of sulfides (i.e. pyrite).
- For the samples that have NAG pH 7, and values of < 5kg H_2SO_4/t (which includes Footwall and Oxide), no acidity is indicated by the NAG pH 4.5 result. This indicates acidity may not relate to sulfide oxidation (i.e. pyrite), but may be due to metalliferous complexing, or very low buffering inherent capacity (i.e. lack of calcium minerals present which is confirmed by low average NAPP values for the Oxide).

44 samples were identified as UC from NAPP values, none of these samples had a NAGpH value lower than pH 6. As a result it is concluded that all the material identified as UC is not likely to be PAF, and is

likely to be NAF. On the basis of these results there is a case to update the block model based on these results to reclassify material from UC to NAF.

A comparison between the predictions of samples as PAF based on the estimated NAPP results and the laboratory NAG test is given in Table 15.

Table 15 Comparison of PAF classification between estimated NAPP values and laboratory NAGpH data*

Lithology type	Number samples PAF NAGpH <4.5	Number samples PAF Estimated NAPP > 10 kg H_2SO_4/t.	Max result NAG@pH7 kg H_2SO_4/t.	Max result Estimated NAPP kg H_2SO_4/t.
BIF North	0	2	<0.5	36.5
BIF South	3	9	15.3	78.5
Oxide	0	0	4	6.8
Hanging Wall	8	11	99	128
Footwall	0	4	0.8	33

*Note that this data only includes samples for which estimated NAPP is available

The results in Table 15 indicate that the method of classifying material as PAF based on the estimated NAPP is overly conservative for all strata other than the Hanging Wall. The following general observations are made:

- In total 26 samples were classified as PAF by the estimated NAPP however only 11 samples were confirmed to be PAF by the NAG test
- 15 samples of the BIF and Footwall materials were classified as PAF by the estimated NAPP however only 3 samples were confirmed to be PAF by the NAG test. This indicates these materials have a much lower risk of being PAF than the estimated NAPP results indicate
- 11 samples of the Hanging Wall materials were classified as PAF by the estimated NAPP and 8 samples were confirmed to be PAF by the NAG test. The Estimated NAPP method appears to more accurately predict the occurrence of PAF materials in the Hanging Wall materials therefore.
- NAPP values calculated by the estimated NAPP method are significantly higher than the actual acidity given by the NAG@pH7 results from laboratory testing for the BIF and Footwall materials.
- The Hanging Wall and Oxide samples appear to have a closer relationship between estimated NAPP and laboratory NAG test results than the BIF or Footwall samples. This fact likely relates to the lower buffering capacity of these material types relative to the BIF and Footwall materials that have much higher ANC values

Based on the Task 1 NAPP values and correlation with the laboratory NAG results, there is a case to update the block model with a higher cut off value to define materials as PAF (currently the adopted cut off is 10 kg H2SO4/t). This relates to the conservatism of the NAPP method in predicting material as being PAF. The results of the NAG testing indicates that a cut off value of 20 kg H2SO4/t may be appropriate.

To determine if this is appropriate fuurther detailed geochemical testing has been carried out to confirm the following:

- The nature of the geochemistry of the material and the related risk of acidic, metalliferous or saline drainage (if this material is to be mined/exposed) to validate the NAG test results.
- The nature of the geochemistry of the material identified as PAF, and the related risk of acidic, metalliferous or saline drainage (if this material is to be mined/exposed).

Kinetic testing has been scheduled to determine if a revision to the cut off value is appropriate.

8.4 Total Metals (XRF) Results

Trace metals are typically screened by comparing them with crustal averages, or against contaminated soil trigger values for environmental protection. The trace metal concentrations in the samples are compared with the average crustal abundance (Berkman and Ryall 1982), as outlined in DME (1995), to produce a Geochemical Abundance Index (GAI). Samples with a GAI of greater than 3 are considered significantly enriched.

As part of DTR test work that has been completed as part of metallurgical work carried out by Fortescue, samples from the Hematite pit were analysed by the laboratory for a number of heavy and base metals using XRF. The results of the analysis were compared against GAI factors to determine if metals were present at elevated levels. The results of this assessment are given in Appendix F, and summarised in Table 16.

The results from XRF testing of material from DTR test work indicates that mineralised material contains on average, elevated concentrations of chromium (mean value for mineralised samples 485.2 mg/kg, EIL 400 mg/kg) and nickel (mean value for mineralised samples 170.8 mg/kg, EIL 60 mg/kg). Average concentrations of the majority of metals within the tailings samples were below EIL levels with the exception of nickel (mean value for non-mineralised samples 106 mg/kg, EIL 60 mg/kg), and arsenic (mean value for non-mineralised samples 22 mg/kg, EIL 20 mg/kg).

In terms of enrichment with respect to GAI, the tailings material identified arsenic to be enriched (GAI value of 3).

Further testing of materials utilising ICP laboratory analysis has been completed to provide additional information on the concentration of heavy and base metals in the material types identified in the deposit.

Table 16 Summary of DTR testing (metals analysis)

Summary	Cr	Ni	Cu	Zn	As	Pb
EIL (mg/kg)	**400**	**60**	**100**	**200**	**20**	**600**
			Cons			
Average conc. (mg/kg)	485.2	170.8	85.4	96.8	5.2	84.6

Average tails (mg/kg)	137.2	106.4	70.5	66.0	22.3	5.4
Max tails(mg/kg)	3600	4600	300	1000	100	70
Min tails(mg/kg)	5	5	5	5	5	5
GAI>3 enriched						
Average GAI Cons	1	0	0	0	1	2
Average GAI Tails	0	0	0	0	3	0

8.5 Acid base characterisation curve assessment

Comparison between laboratory NAPP values and estimated NAPP values indicated that some material types (BIF South, BIF North and Footwall) may have higher buffering capacity than indicated by the Estimated NAPP results. A more accurate estimation of the likely field neutralising potential of a material can be gained from the acid base characterisation curve (ABCC).

48 samples were tested using the ABCC method. Two titration end points have been used by GHD to interpret the test results which have been taken from the curves presented by the laboratory):

- Buffering capacity at pH 4.5, this value indicates the amount of acidity that can be buffered by the material to retain a pH above 4.5. This is considered the total available buffering capacity of the material.
- Buffering capacity at pH 6.5, this value indicates the amount of acidity that can be buffered by the material to retain a pH above 6.5. This is considered the total easily liberated buffering capacity of the material that can maintain a near neutral pH.

The results indicate the following:

- Lab ANC values are approximately twice as high as estimated ANC values for all strata types. This is anticipated as laboratory ANC testing will include non calcium based buffering minerals such as siderite. This observation provides evidence to suggest that estimated NAPP values are therefore conservative estimates of potential buffering capacity.
- Buffering capacity values at pH 6.5 are relatively low compared to laboratory derived total ANC, around 6-20% of total ANC is liberated at pH 6.5.
- Buffering capacity values at pH 4.5 are significantly higher than at pH 6.5, with 24-68% of the total ANC liberated.
- The BIF South has the highest proportion of laboratory derived total ANC liberated at pH 4.5 at 68%; the Hanging Wall has the lowest at 24%.
- The estimated ANC values under predict the buffering capacity of the BIF materials (North, South and Oxide). Greater than 100% of the estimated ANC is liberated at pH 4.5, with an average of 150% liberated by at pH 4.5 by the BIF South materials. This indicates that for these materials the estimated ANC values are very conservative.
- In similarity with the lab ANC values, the estimated ANC values appear to over predict the buffering capacity of the Hanging Wall and Footwall materials. However, the estimated ANC values are much

closer to the actual buffering capacity indicated by the pH 4.5 results than the laboratory ANC values. 85% of the estimated ANC is liberated at pH 4.5 for the Footwall materials compared to 51% of laboratory derived ANC, and 52% of the estimated ANC is liberated at pH 4.5 for the Hanging Wall materials compared to 24% of laboratory derived ANC.

- The BIF South materials appear to have moderate to high net acid consuming properties and have minerals that appear to produce easily liberated alkalinity that will likely result in buffering between the pH range 6.5-4.5.

The findings of the laboratory NAG testing are complemented by the results of the ABCC testing as:

- The NAG testing results indicated that the estimated NAPP method tended to overestimate the number of samples being classified as PAF in all materials other than the Hanging Wall.
- The ABCC results indicate that the effective buffering capacity of the materials (as indicated by the buffering to pH 4.5 results) is underestimated for all the BIF materials, but overestimated for the Hanging Wall materials

It is concluded therefore that the estimated NAPP method is a conservative method for identifying and classifying material as PAF for the majority of the material types and will likely overestimate the volume of material that has a high risk of being PAF. The exception to this is the Hanging Wall materials which are likely to be more accurately classified as PAF. The NAG testing results support this observation.

Further, it is concluded that the BIF South materials appear to have moderate to high net acid consuming properties and have a mineralogy that appears to produce easily liberated alkalinity that will likely result in buffering between the pH range 6.5-4.5.

8.6 XRD

47 samples were submitted for XRD analysis to determine the mineralogy of the material types. A summary of the results is given in Table 17:

Table 17 XRD Data

Lithology type	Major components	Minor components	Trace components
BIF North	Quartz	Chamosite, microcline, magnesioferrite, magnetite, siderite, clinochlore	Dolomite, hydroxyl-apatite, stilpnomelane, hematite, kaolinite
BIF South	Quartz, magnetite	Hydroxyl-apatite, stilpnomelane, dolomite, chlorite-serpentine, siderite, microcline	Kaolinite, cryptohalite, pyrophanite
Oxide	Quartz, goethite	Stilbite, iron oxide ($Fe_5.34O_8$), hematite	Clinochlore, magnetite, stilpnomelane
Hanging Wall	Quartz, muscovite	Clinochlore, siderite, chamosite, stilpnomelane,	Hematite, kaolinite, magnetite, goethite, dolomite, cryptohalite,

		magnesioferrite, chlorite-serpentine	ganterite
Footwall	Quartz, ekmanite (Mn-rich stilpnomelane/smectite)	Stilbite, magnetite, stilpnomelane, kaolinite, siderite, magnesioferrite, clinochlore	Hematite, dickite, dolomite, cryptohalite, ankerite

The XRD analysis indicates that the four main material types have a different dominant mineralogy.

- The BIF materials are dominated by quartz and the iron bearing magnetite as would be expected from the geological data. Minerals with potential acid buffering capacity are present including dolomite and siderite. It is these minerals that are the likely source of the high buffering potential of the BIF South material as indicated from ANC and ABCC testing. Low temperature metamorphic group minerals include microcline, stilpnomelane and chlorite group minerals (including clinochlore, chamosite and chlorite-serpentine) which indicate metamorphism of the amphibolite facies.
- The Oxide is dominated by quartz and goethite, relatively minor iron bearing minerals (hematite, magnetite and iron oxides). Relative to the other material types analysed by XRD, the Oxide samples have fewer minor and accessory minerals. This may be due to preferential weathering of the minor and trace minerals. The low acid buffering capacity of the Oxide, as indicated by ANC and ABCC tests, is evidenced by the paucity of buffering minerals such as dolomite and siderite, which are present in the fresh BIF materials.
- The Footwall is dominated by quartz and ekmanite (Mn-rich stilpnomelane), indicating a different major minerals assemblage relative to the BIF and the Hanging Wall. Low temperature metamorphic group minerals include stilpnomelane and chlorite group minerals, including clinochlore, which indicates metamorphism of the amphibole facies. Minor and trace minerals including siderite, dolomite and ankerite are the likely sources of the acid buffering potential indicated to be present in this material by ANC and ABCC testing. Kaolinite and dickite are found as minor components, indicating the Footwall may have an appreciable clay component (shale). Stilbite, which is a zeolite clay, is present indicating the material may have a high cation exchange capacity. Stilbite is often associated with calcite which, if present, offers a high degree of acid buffering potential.
- The Hanging Wall material is dominated by quartz and muscovite. The presence of muscovite along with stilpnomelane and chlorite group minerals (including chamosite and chlorite-serpentine) indicates low to medium grade metamorphism of the amphibole facies. Pyrite was not detected by the XRD, however was observed in the geological logs from visual observations. Samples of Hanging Wall material obtained from hole number NS107 that were subject to XRF analyses had high NAPP values and are classified as PAF. These samples have muscovite present as a major mineral. It is possible that the pyrite present in these samples is related to the medium grade metamorphic assemblage of chlorite-serpentine, chamosite and muscovite. Minor amount of acid buffering minerals are present, including dolomite and siderite. It is noted that from ANC and ABCC testing that the Hanging Wall has generally lower buffering capacity than the Footwall or BIF materials. Kaolinite is present in trace amounts indicating that clay minerals are present (shale). Iron mineralisation is indicated by the presence of hematite, goethite and magnetite.

8.7 Kinetic NAG

11 Kinetic NAG tests were carried out to determine the relative reactivity of the samples that were identified as PAF from the NAG tests. Results are shown in Table 18. In general, the samples with the highest NAPP values were chosen form BIF South and Hanging Wall material types, along with some lower grade PAF material of these material types.

Table 18 Kinetic NAG Data

Lithology type	BH and depth	NAPP kg/t H_2SO_4	Maximum temperature (ºC)	Time to maximum temperature (minutes)
BIF South	NS0077 178-180m	78.4	27	360
Hanging Wall	NS0084 158-160m	20.6	20.8	70
BIF South	NS0096 230-232m	16	22	70
Hanging Wall	NS0107 120-122m	93	64	40
Hanging Wall	NS0107 128-130m	78	61	65
Hanging Wall	NS0107 140-142m	48	63	100
Hanging Wall	NS0107 148-150m	57	51	100
Hanging Wall	NS0107 160-162m	49	52.5	100
Hanging Wall	NS0107 170-172m	37	55	150
BIF South	NS0120 206-208m	28	30.8	315
Hanging Wall	NS0153 200-202m	128	75	30

The following general observations have been made:

- Samples of highly PAF Hanging Wall material (NAPP>50 kg H_2SO_4/t) from boreholes NS107 and NS153 appear to be relatively reactive as the tests returned maximum temperatures of greater than 70ºC, and the time taken to reach the maximum temperature was of a short duration of 40 minutes or less. The lower grade PAF materials appear to be significantly less reactive, as maximum temperatures reached in any of the tests was 20.8 ºC for material with a NAPP of <35 kg H_2SO_4/t.
- The sample of the BIF South material from borehole NS077, although highly PAF (NAPP >50 kg H_2SO_4/t), does not appear to be reactive as the maximum temperature reached was only 27 ºC and the time taken to reach this temperature was 320 minutes. The other BIF South samples tested were also not fast reacting, with the maximum temperature reached in any of these tests being 30.8 ºC.

The results of the testing confirm the findings of the NAG tests and ABCC tests, which indicated that the BIF South has significant buffering capacity. The kinetic test results indicate that with respect to the BIF South material, the easily liberated acid buffering capacity appears to mediate the sulfide oxidation reactions such that they proceed at a slow rate. The Hanging Wall materials were indicated by the NAG tests and ABCC tests to have lower buffering capacity than the BIF South materials. This is supported by the kinetic NAG tests which indicate that for material with high NAPP values (NAPP >50 kg H_2SO_4/t), the sulfides present oxidise relatively quickly, and the reaction is highly exothermic.

8.8 Total Metals

To validate the findings of the XRF metals analysis supplied by Fortescue, 140 samples were submitted for total metals analysis (ICPMS) and are presented in Appendix F. The results indicate that compared to the average crustal abundance (based on the Global Abundance Index where enrichment greater than three times the average crustal abundance is considered significant), no metals analysed has an average concentration that is considered to be enriched. The detection limit for Se is higher than the average crustal abundance index, therefore this metal is reported to be enriched in the table of results, but this is an artefact of the elevated detection limit.

The results of the ICPMS analysis validate the XRF data and confirm that base and heavy metal concentrations are generally low for all material types.

Metal results were also compared to EIL values as a conservative means of assessing environmental risk:

- For mineralised material, only Mn has an average concentration higher than EIL values (Appendix F). Minor exceedances of As, Ni and Cd were noted in a very small number of samples, however these exceedances are not considered to be significant given the majority of samples had levels far lower than EIL values.
- For non-mineralised material, Mn and Ni had average concentrations higher than EIL values (Appendix F). The average value for Ni appears to be skewed by high results in a small number of samples as 29 of the 140 samples analysed had Ni concentrations higher than EIL values, with the highest Ni concentration in samples of the Hanging Wall and Footwall materials. Minor exceedances of As, Cd, Cr, Co, V and Hg were noted in a very small number of samples, however these exceedances are not considered to be significant given the majority of samples had levels far lower than EIL values.

In summary, the results indicate that relative to global crustal abundance indicators, heavy and base metal concentrations are generally low for all material types tested. With respect to EIL levels,

manganese (although this is not generally considered to be an ecologically toxic metal), levels are generally elevated in all material types, and elevated nickel levels are indicated in a number of Footwall and Hanging Wall materials. The risk of significant metalliferous drainage impacted based on these results is therefore considered to be low.

8.9 Leaching Assessment

To determine the potential for metalliferous and saline drainage impacts, an assessment of the potential for leaching of metals was carried out. ASLP leach tests were performed on 113 samples and in addition, analysis of the liquor from NAG tests on these same samples was also carried out. Analysis for ASLP testing included base/heavy metals, cations and anions and acidity and alkalinity. Analysis for NAG liquor testing included base/heavy metals analyses. A summary of the results is given in Table 19:

Table 19 Leaching Assessment (ASLP Testing)

Lithology type	Metalliferous leaching	Saline leaching	Alkalinity/acidity
BIF South	Very low levels of metals in majority of ASLP tests. Elevated Zn, Fe, Cu, Al in one sample.	Low total levels of cations and anions (<100 mg/L total) in majority of ASLP leach tests. Sulfate >100 mg/L in two tests.	Low to moderate levels of alkalinity in ASLP leach tests (<50 mg/L $CaCO_3$). Low levels of acidity (maximum acidity 9 mg/L $CaCO_3$). pH>7 in all tests.
Hanging Wall	Very low levels of metals in majority of ASLP tests.	Low total levels of cations and anions (<100 mg/L) in majority of ASLP leach tests. Sulfate >100mg/L in four tests.	Low to moderate levels of alkalinity in ASLP leach tests (<50 mg/L $CaCO_3$). Low levels of acidity in majority of samples, acidity >10 mg/L $CaCO_3$ in three tests. pH <7 in five samples. pH >5 in all tests.
Footwall	Very low levels of metals in majority of ASLP tests. Three samples elevated in Cu, Ni, Fe, Al, Co, Cd, Mn, Zn.	Low total levels of cations and anions (<100 mg/L) in majority of ASLP leach tests.	Low to moderate levels of alkalinity in ASLP leach tests (<50 mg/L $CaCO_3$). Low levels of acidity (maximum acidity 4 mg/L $CaCO_3$). pH >7 in all tests.
BIF North	Very low levels of	Low total levels of	Low to moderate

	metals in majority of ASLP tests. One sample elevated in Cu, Ni, Co, Mn and Zn.	cations and anions (<100 mg/L) in majority of ASLP leach tests. Sulfate >100 mg/L in one test.	levels of alkalinity in ASLP leach tests (<50 mg/L $CaCO_3$). Low levels of acidity in majority of samples, acidity >10 mg/L $CaCO_3$ in one test. pH >7 in all tests.
Oxide	Very low levels of metals in majority of ASLP tests. One sample elevated in Mn. Three samples elevated in Zn, one sample elevated in Cu, one sample elevated in Co and one sample elevated in Ni.	Very low total levels of cations and anions (<50 mg/L) in majority of ASLP leach tests.	Low levels of alkalinity in ASLP leach tests (<15 mg/L $CaCO_3$). Low levels of acidity in majority of samples, acidity >10 mg/L $CaCO_3$ in two tests. pH <7 in two tests, pH >5.5 in all tests.

The results of the ASLP leach testing indicates the following:

- Concentrations of cations and anions are very low in all tests carried out. As a result it is likely that all materials tested have a very low short to medium term risk of generating saline leachate on contact with water.
- Alkalinity levels are higher than acidity levels in the majority of tests carried out, and the pH of the leachate is greater than 7 in the majority of tests. As a result, it is likely that the majority of materials tested have a very low short to medium term risk of generating acidic leachate on contact with water.
- Concentrations of metals are generally very low (below detection limits) in the majority of tests carried out. As a result, it is likely that the majority of materials tested have a very low short to medium term risk of generating metalliferous leachate on contact with water.
- The results from a small number of samples indicate slightly acidic pH (between pH 5 and pH 7), elevated sulphate levels (>100 mg/L) and elevated metals. These samples generally corresponds with material that has been identified as PAF from NAPP results and laboratory NAG tests. As a result, material identified as PAF may have an increased risk in the short to medium term of generating leachates that are acidic, metalliferous and/or saline.

8.10 NAG Liquor Analysis

Analysis of the liquor from the NAG tests was carried out to determine what metals are liberated from complete sulfide oxidation into the dissolved phase. The test results indicate the total mass of metals that may be liberated as a result of complete oxidation of the material so therefore will significantly overestimate the likely leachate strength that may result from *in situ* weathering in the field.

General observation from the testing are as follows:

- Concentrations of metals were generally elevated in all tests relative to the ASLP test results. Elevated levels of Fe, Al, Mn, Ni, Zn, Cu, Cd and Hg were noted in the majority of tests;
- Concentrations of metals were generally lower in tested completed on the oxide material;
- Concentrations of the majority of metals were generally not significantly higher in samples of material identified as PAF than in samples not identified as PAF. However, concentrations of As and Ni were notably higher in the tests completed on Hanging Wall material (NS0107, NS0153) with high NAPP values; and
- Concentrations of metals were broadly similar between the BIF, Footwall and Hanging Wall materials.

Conclusions made with respect to the observations made above are:

- The Oxide material appear to contain low levels of metals that can be easily liberated by oxidation reactions;
- Other than Fe, Mn and Al, all base and heavy metal concentrations for all samples are below 1 mg/L. Significant metalliferous discharges are therefore not likely to occur from the materials tested;
- PAF material (i.e. high NAPP values) identified in Hanging Wall samples from NS0107 and NS0153 produced liquor with the highest concentrations of Ni and As. These metal species therefore appear to be liberated by oxidation of sulfides present and may be associated with the sulfide mineralisation; and
- With the exception of some samples of the Hanging Wall material identified as PAF< in general, total metal concentrations form the tests were not significantly higher for a particular material type. Therefore, it is concluded that the risk of metalliferous drainage occurring is not significantly higher for any material type other than the Hanging Wall material identified as PAF.

8.11 Tailings Assessment

Two representative samples of tailings materials (one of dry tailings and one of wet tailings) were provided by FMG from the trial processing being undertaken as part of metallurgical testing. The samples were analysed for: NAG, NAPP, total metals, ASLP leach test (deionised water), ASLP leach test (acetic acid leach), NAG liquor, paste pH, ABCC, and XRD.

The results (provided in Appendix E) indicate the following:

- NAG pH and NAPP results indicate the tailings materials are NAF, and have potential buffering capacity (NAPP values of around -50 kg H_2SO_4/t; average NAG pH of 9.1);
- ABCC tests indicate that available buffering capacity is approximately 30% of the laboratory ANC. The estimated ANC based on calcium concentrations that has been used by GHD for modelling is more conservative than laboratory ANC calculations and results in a lower value than laboratory ANC. There is good correlation between ABCC results and estimated ANC. This method appears to be more accurate than the laboratory ANC which tends to overestimate actual ANC;
- XRD analysis indicates that there are carbonate minerals present that are the likely source of the ANC. These include the iron carbonate siderite and ankerite which is a calcium containing carbonate. Siderite is known to be a poor buffering mineral which likely explains the lab ANC value being

elevated relative to the ABCC analysis results. Ankerite is likely to be the main buffering mineral present which explains the close correlation between estimated NAPP values used for modelling that are based on calcium and ABCC values. No sulfides were detected from XRD analysis;

- Total metals analysis indicates low concentrations of all metals (relative to average crustal abundance index and EIL levels), with the exception of arsenic; the risk of metalliferous drainage is therefore considered to be limited;
- ASLP leach testing indicates that when leached with deionised water an alkaline leachate is produced which has moderate alkalinity levels (50 mg/l), low concentrations of metals (relative to ANZECC freshwater criteria), low salinity, and no acidity. The results indicate that the tailings materials are relatively inert and on contact with fresh water are not likely to produce saline or acidic discharges. The moderate alkalinity levels detected in the leachate indicates that soluble carbonate minerals may be present in the material;
- NAG liquor leachate analysis indicates that complete oxidation of the material does not result in the release of high levels of soluble metals; and in general, metal concentrations are low relative to ANZECC freshwater criteria. Salinity levels are also low indicating the potential for saline discharges is low as a result of direct oxidation of these materials; and
- Based on the Task 1 analysis, a NAPP value cut off for classification of tailings material as NAC is < -50 kg H_2SO_4/t. Although the laboratory ANC values are around 300% higher than the estimated NAPP value, ABCC testing indicates that about 30% of the ANC is easily liberated and is likely to contribute to buffering of acidity. On this basis it is recommended that the cut off value is retained for assessment of material as NAC.

9. Geochemical Characterisation of Material

Based on a detailed analysis of the geology, assay data (XRF results for calcium and sulfur), detailed testing and geochemical modelling that have been carried out to date; GHD makes the following conclusions regarding the likely AMD characteristics of the material.

9.1 High Level Review

- A review of geological, mineralogical and assay test data for the lithology types identified in the pit shell indicates that sulfide minerals (pyrite) are likely to be present within some zones of the deposit. The most frequent occurrence of sulfidic materials (i.e. pyritic) is generally found within the Hanging Wall, the Footwall and within the BIF-South units. There appears to be generally lower levels of sulfidic material present within the BIF-North unit, and very little present in the Oxide materials. The Hanging Wall comprising the greatest quantity of sulfidic minerals of all material types.
- GHD has calculated NAPP values for all data points within the existing assay database for the North Star Magnetite pit based on the ratio of sulfur to calcium (corrected for stoichiometric ratios) as determined by laboratory XRF analysis. Statistical analysis of the geochemical database constructed by GHD indicates that the majority of the materials within the pit shell have a NAPP value between -20kg and 0 H_2SO_4/t. The summary statistics for all the calculated NAPP data within the pit shell indicates that with a mean value of -10kg H_2SO_4/t, the majority of materials in the pit are not likely to pose a high risk of producing acidity from sulfide oxidation.
- Calcium to sulfur ratios for data points within the geochemical model were determined by GHD. From these ratios it is apparent that in general the BIF units have a greater number of negative NAPP values than the Hanging Wall or Footwall which is likely the result of higher calcium concentrations and lower sulfur concentrations. The average calcium to sulfur ratio across the whole database is 13, with a median of 6, indicating that in general, the materials in the database are not likely to be PAF.
- If the calcium containing mineral phases present within much of the BIF materials are freely available (i.e. present in soluble carbonate forms) then the data indicates that the majority of these materials may be net acid consuming (albeit at low levels).
- As part of DTR test work, samples were analysed by the laboratory for a number of heavy metals using XRF. The results of the analysis were compared against Global Abundance Index (GAI) factors and EILs (Environmental Investigation levels) to determine the presence of elevated metal concentrations. The results of this assessment are provided in Appendix F. The results indicate that all the material tested has low metals concentrations when compared against the GAI index (with the exception of arsenic in the tailings material) and EIL levels (DEC assessment criteria). Further testing of materials utilising ICP laboratory analysis is planned to provide additional information on the concentration of metals in the material types identified in the deposit.
- No assay data was available for much of the waste material which forms the majority of the western zone of the deposit within the Hanging Wall; as a result, an assessment of the geochemistry of these materials was not possible at this time. Material in this zone comprises approximately 40% of the overall volume in the pit shell, and the majority of this zone comprises waste rock. Therefore, significant uncertainty remains as to the volume of PAF materials that may be generated by mining activities at the site.

- The relationship between sulfur concentrations and iron grade, in addition to sulfur and calcium concentrations was assessed to determine mineralogical relationships between these parameters. The following conclusions have been reached:
    - In general sulfur and iron grades are inversely proportional. That is to say, non-mineralised (i.e. waste materials) units have higher sulfur grades than mineralised (ore) units.
    - In general there is no relationship between calcium and sulfur concentrations; however, sulfur concentrations were higher in non-mineralised (i.e. waste) units which were not associated with a concomitant increase in calcium concentrations. Therefore the sulfur: calcium ratio for non-mineralised units is lower than for mineralised units.
- The implication of the relationships noted above is that waste rock and ore (and therefore tailings) are not likely to have very similar geochemical characteristics with respect to acidity generating potential. In general the mineralised lithologies (BIF) are more likely to be characterised as NAF, whereas PAF materials are more likely to occur within the non-mineralised materials (Hanging Wall and Footwall).
- Average NAPP values for each lithology has been determined as follows:
    - Oxide: -1.2kg H_2SO_4/t
    - Hanging Wall: -2.5kg H_2SO_4/t
    - BIF-North: -9.3kg H_2SO_4/t
    - Footwall: -11.7kg H_2SO_4/t
    - BIF-South: -17.9kg H_2SO_4/t
- The average NAPP value indicate that the Oxide and Hanging Wall materials have the lowest potential buffering capacity (based on calcium content), with the BIF-South having the highest potential buffering capacity (based on calcium content).

9.2 Detailed Testing (Tasks 2-3)

Detailed geochemical testing has been carried out on approximately 1,163 samples collected from core and chips to date representing the range of potential waste material types likely to be encountered within the pit. Detailed testing includes NAG and a limited number of NAPP tests.

In addition to testing of core and chips, two samples of tailings materials from processing trials have been subject to detailed testing including NAG, NAPP, total metals, ASLP leach tests (deionised water and acetic acid leach tests), NAG liquor analysis, paste pH, ABCC and XRD analysis.

Laboratory NAG pH results from the 1,163 core and chip samples indicate that:

- 11 samples were classified as PAF (3 samples of BIF-South, and 8 samples of Hanging Wall);
- 67 samples were classified as uncertain (UC). The majority of samples classified as UC were from the Hanging Wall, Footwall, Oxide and BIF-South units;
- All other samples were classified as NAF; and
- All samples of material with estimated NAPP values of <15kg H_2SO_4/t were not classified as PAF according to laboratory NAG test data.

Where laboratory NAPP testing (151 samples) was undertaken, a comparison of the results against the estimated NAPP from Task 1 was completed by plotting the results on a box plot. In general, the laboratory NAPP values were lower than the estimated NAPP value. This was perhaps to be expected as the laboratory NAPP test assumes all carbon present is present as reactive calcite, and are therefore somewhat conservative. .

The results of the NAG testing received to date correlated well against the Task 1 provisional classifications based on an estimated NAPP value. It is noted that in 14 cases the estimated NAPP value classified material as PAF (based on a cut off for NAPP of >10kg H_2SO_4/t) when laboratory NAG test data indicated the material to be UC or NAF. No samples of material with estimated NAPP values of <15kg H_2SO_4/t were classified as PAF according to laboratory NAG test data. On this basis it is considered that the estimated NAPP values in the geochemical database are likely to be conservative and are more likely to overestimate the volume of materials classified as PAF than underestimate.

Based on the ABCC testing it is concluded that:

- The estimated NAPP method is a conservative method for identifying and classifying material as PAF for the majority of the material types and will likely overestimate the volume of material that has a high risk of being PAF. The exception to this the Hanging Wall materials which are likely to be more accurately classified as PAF. The NAG testing results support this observation.
- Further, it is concluded that the BIF South materials appear to have moderate to high net acid consuming properties and have a mineralogy that appeared to produce easily liberated alkalinity that will likely result in buffering between the pH range 6.5-4.5.

The results of the Kinetic NAG testing appear to confirm the findings of the NAG tests and ABCC tests which indicated that:

- The BIF South has significant buffering capacity. The kinetic test results indicate that with respect to the BIF South material, the easily liberated acid buffering capacity appears to mediate the sulfide oxidation reactions such that they proceed at a slow rate.
- The Hanging Wall materials were indicated by the NAG tests and ABCC tests to have lower buffering capacity than the BIF South materials. This is supported by the Kinetic NAG tests, which indicate that for material with high NAPP values (NAPP >50 kg H_2SO_4/T) the sulfides present oxidise relatively quickly, and the reaction is highly exothermic.

Total metals analysis results (based on XRF and ICP analysis) indicate that relative to global crustal abundance indicators, heavy and base metal concentrations are generally low for all material types tested. With respect to EIL levels, Mn (although this is not generally considered to be an ecologically toxic metal) levels are generally elevated in all material types, and elevated Ni levels are indicated in a number of Footwall and Hanging Wall materials. The risk of significant metalliferous drainage impacts based on these results is therefore considered to be low.

Based on ASLP leach testing, the short term risks of acid, saline or metalliferous drainage appear to be low:

- Concentrations of cations and anions were very low in all tests carried out. As a result, it is likely that all materials tested have a very low short to medium term risk of generating acidic leachate on contact with water.

- Alkalinity levels are higher than acidity levels in the majority of tests carried out, and the pH of the leachate is greater than 7 in the majority of tests. As a result it is likely that the majority of materials tested have a very low short to medium term risk of generating acidic leachate on contact with water.
- Concentrations of metals are generally very low (below detection limits) in the majority of tests carried out. As a result, it is likely that the majority of materials tested have a very low short to medium term risk of generating metalliferous leachate on contact with water.
- The results forma a small number of samples indicate slightly acidic pH (between pH 5 and pH 7), elevated sulphate levels (> 100 mg/L) and elevated metals. These samples generally correspond with material that has been identified as PAF from NAPP results and laboratory NAG tests. AS a result, material identified as PAF may have an increased risk in the short to medium term of generating leachates that are acidic, metalliferous and/or saline.

Based on NAG liquor analysis, the risks of metalliferous drainage as a result of *is situ* oxidation of materials does not appear to be high considering:

- The Oxide material appears to contain low levels of metals that can be easily liberated by oxidation reactions;
- Other than Fe, Mn and Al all base and heavy metal concentrations for all samples are below 1 mg/L. Significant metalliferous discharges are therefore not likely to occur from the materials tested;
- PAF material (i.e. high NAPP values) identified in Hanging Wall samples from NS0107 and NS0153 produced the liquor with the highest concentrations of Ni and As. These metal species therefore appear to be liberated by the oxidation of sulfides present, and may be associated with the sulfide mineralisation; and
- With the exception of some samples of the Hanging Wall material identified as PAF, in general, total metal concentrations from the tests were not significantly higher for a particular material type. There, it is concluded that the risk of metalliferous drainage occurring is not significantly higher for any material type other than the Hanging Wall material identified as PAF.

9.3 Geochemical Classification

Based on the results obtained from the laboratory testing carried out to date the following conclusions are reached regarding classification of material within the geochemical database:

- Material with NAPP values of >15kg H_2SO_4/t is likely to be PAF;
- Material with NAPP values of between 0-15kg H_2SO_4/t is very unlikely to be PAF, and likely to be NAF based on laboratory NAG test data;
- Material with NAPP values of <0kg H_2SO_4/t is likely to be NAF.

With respect to applying geochemical classification criteria within the geochemical database and future geochemical modelling, the following is recommended:

- For conservatism (allowance of factor of safety), it is considered appropriate that a cut off value of 10kg H_2SO_4/t is retained for classifying material as PAF in the geochemical database;
- Material with NAPP values between 0-10kg H_2SO_4/t although likely to be NAF, shall be classified as UC pending the results of additional detailed testing (which has been scheduled by GHD);
- Material with NAPP values <0kg H_2SO_4/t is likely to be NAF; and

- Material with NAPP values < -30kg H_2SO_4/t is likely to be NAC according to ABCC results.

9.4 Tailings Assessment

Two representative samples of tailings materials (one of dry tailings and one of wet tailings) were provided by FMG from the trial processing being undertaken as part of metallurgical testing. The samples were analysed for: NAG, NAPP, total metals, ASLP leach test (deionised water), ASLP leach test (acetic acid leach), NAG liquor, paste pH, ABCC, and XRD.

The results (provided in Appendix E) indicate the following:

- NAG and NAPP results indicate the tailings materials are NAF, and have potential buffering capacity (NAPP values of around -50kg H_2SO_4/t).
- ABCC tests indicate that the available ANC is approximately 30% of total ANC, the low proportion of available ANC is likely to be a result of carbonate minerals being present that are not easily liberated. This being said the tailings materials still process appreciable buffering capacity of around 15kg H_2SO_4/t.
- XRD analysis indicates that there are carbonate minerals present in the samples. These include the iron carbonate siderite, in addition to ankerite; the latter being an iron and manganese containing calcium carbonate. Ankerite is likely to be the main buffering mineral present, which may explain the close correlation between estimated NAPP values(used for modelling and based on calcium) and ABCC values.
- Total metals analysis indicates low concentrations of all metals (relative to EIL levels) with the exception of manganese in the tailings material; the risk of metalliferous drainage is therefore considered to be limited.
- ASLP leach testing indicates that the tailings materials are relatively inert and on contact with fresh water are not likely to produce saline or acidic discharges. The moderate alkalinity levels detected in the leachate indicates that partially soluble carbonate minerals may be present in the material.
- When leached with acetic acid (to simulate interaction with AMD leachate) the tailings materials produced a leachate with low concentrations of most metals (relative to ANZECC freshwater criteria), and moderate levels of salinity (1,500mg/l Na). Sodium levels in the leachate are elevated relative to calcium and magnesium levels indicating that sodic discharges may be produced as a result of interaction (buffering reactions) between the tailings material and AMD discharges.
- NAG liquor leachate analysis indicates that complete oxidation of the material does not result in the release of high levels of soluble metals; in general metal concentrations are low relative to ANZECC freshwater criteria. Salinity levels are also low indicating the potential for saline discharges is low as a result of direct oxidation of these materials.
- Based on detailed testing results a NAPP cut off value for classification of tailings material as NAC is <-30kg H_2SO_4/t.

9.5 Geochemical Block Modelling: Volume Estimates

Although statistical analysis has provided useful indication of the relative fractions of the lithology types that may be classified as PAF, the technique does not translate well to estimating volumes of material within a resource.

Two models have been run as a result of the uncertainty associated with the lack of drill data which comprises approximately 40% of the volume of the pit shell.

Modelling indicates the following:

- The Hanging Wall contains a high proportion of PAF material (41,648,750 m^3). With respect to overall volumes of PAF calculated by the model within the model space, the majority of PAF is found within this lithology type.
- The BIF does not appear to contain significant volumes of PAF by overall proportion, although it is noted that PAF material has been modelled to occur within this lithology type. Although PAF has been identified a more significant proportion of the BIF has been identified to be NAC. The presence of the NAC material on a ratio of approximately 10:1 with respect to PAF material is relevant when considering the overall classification for the BIF is likely to be NAF.
- The Oxide contains appreciable levels of PAF and UC. The presence of this volume of PAF is not expected from the Task 1 review which indicates the Oxide has low sulfur levels. The modelled PAF volumes are considered to be an artefact of the nature of the model extrapolation of data. The model is extrapolating the presence of sulfidic material based on sub vertical dipping geology. Where there is limited drilling data at the surface (which occurs in the west of the model due to the boreholes being inclined to the west) the model has extrapolated the presence of sulfidic material from depth and projected to surface. All other testing has shown there to be no PAF in the Oxide.
- A significant volume of material has been identified as UC; although low risk with respect to AMD as a result of NAPP values being < 10 kg H_2SO_4/t, further detailed testing is required to confirm if this material is likely to be NAF or PAF.

The model results broadly agree with the high level statistical analysis, however, the volume estimates differ when comparing classes of material within each lithological unit. The main reason for this difference is that the model has extrapolated data between boreholes based on the fact that the model has been set up to follow the strike and dip of the prevailing geology. The extrapolation of material as PAF for example has been determined by assumption that the PAF material occurs as continuous blocks of material orientated north south with a sub vertical dip. This is not accounted for in the statistical analysis.

The total volume of PAF estimated by the model is approximately 47,632,500 m^3, with the majority of this is found within the Hanging Wall material. The eventual waste stream this materials reports to (i.e. tailings or waste rock) will depend on the eventual classification of these materials as waste or ore within the mine model. The volumes of PAF projected to report to the waste rock dump and tailings stream should be revised once the resource model has been completed. Further drilling in the west of the deposit will allow the model to be refined to allow more accurate classifications of PAF materials in the Hanging Wall material.

9.6 Summary

A high level and detailed characterisation exercise has been completed by GHD as part of this report. Risks of AMD discharges developing are considered at this stage to be low for the majority of the materials within the pit shell given:

- The mineralogy of the tested material;

- The sulfur content of the tested material (note that elevated concentrations may be present within the BIF, Hanging Wall and Footwall);
- The excess neutralisation capacity of the tested material;
- The low content of metals within the materials (with the exception of iron and aluminium); and
- The low potential for the material to produce metalliferous, acidic or saline discharges.

This being said, a realtively small proportion of the Hanging Wall, Footwall and BIF material has been identified as PAF and is a potential source of AMD.

The long term stability of the material to be stored within the pit can be estimated by geochemical modelling. Model parameters that influence AMD discharge potential are provided in Table 20.

Table 20 Summary of Predictive Geochemical Parameters

Parameter	Assessment
pH of leachate	No acidic leachate likely to be produced by majority of materials. Some Hanging Wall material may produce acidic leachate.
Dissolved metals concentrations	Likely to be low, given low metal concentrations. To be assessed through further testing.
Net alkalinity/acidity of leachate	Likely to be net alkaline for majority of materials. Some Hanging Wall material will likely produce net acidic leachate.
Salinity	To be assessed through further testing. Some Hanging Wall material may produce leachate with elevated sulphate levels as a result of sulphate oxidation.
Sulfide oxidation	Minor elevated sulfur levels in BIF and Footwall, major elvelated levels in Hanging Wall materials. Kinetic testing indicates sulfide reaction rates are slow in the BIF due to buffering reactions, however reaction rates in the Hanging Wall material are rapid.
Carbonate dissolution	Soluble calcium carbonate mineral phases likely to be present in Footwall and in particular the BIF South materials based on ABCC testing.
Formation of secondary mineral phases	Possible as a result of AMD discharges from Hanging Wall materials.

Based on lithological specific analysis, detailed geochemical testing, and statistical analysis of the geochemical data set it appears that:

- The BIF material is considered to be NAF. A small proportion of PAF material has been identified in the BIF-South based on a NAPP cut off of >15 kg H_2SO_4/t. Laboratory testing has confirmed the material is likely to be PAF. However, this material is likely to be slow reacting and has low metal content and therefore is not likely to present a high risk of producing AMD.
- The majority of the Hanging Wall material is NAF; however, there is a significant PAF component based on estimated NAPP values. Laboratory testing has confirmed this material is likely to be PAF. This material is likely to be fast reacting based on kinetic testing and so is at a high risk of producing acid leachates. However, metal content is low, therefore the risk of metalliferous drainage is not high. A UC component has been identified with 9% of material classifying as UC based on estimated NAPP values. Laboratory testing has indicated this material is likely to be NAF and not likely to produce saline or metalliferous drainage.
- The majority of the Footwall material is NAF; however there is a minor PAF component. A significant UC component has been identified, however laboratory testing has indicated this material is likely to be NAF and is not likely to produce saline or metalliferous drainage.
- The majority of the Oxide is NAF; however, there is a significant UC component. Laboratory testing has indicated this UC material is likely to be NAFand is not likely to produce saline or metalliferous drainage.
- With respect to tailings materials, some of the BIF-South material may be acid consuming based on ABCC lab testing results. These results confirm that calcium is likely to be present as a readily liberated carbonate. Approximately 20% of the material has a NAPP value of -30kg H_2SO_4/t or lower.

The total volume of PAF within the Magnetite pit estimated by the model is approximately 47,632,500 m^3. This is found within the Oxide (2,906,875 m^3), BIF-North (1,113,125 m^3), BIF-South (1,064,375 m^3), Footwall (899,375 m^3) and Hanging Wall (41,648,750 m^3) material. However, due to the thinly bedded nature of the BIF material, the relatively coarse drill spacing of exploration drilling and the variable depth of the oxide, there remains uncertainty over the possibility that additional PAF material may be encountered during mining activities that extend beyond the base of the Oxide.

As result of the extrapolation of data by the model, some Oxide material has been classified as PAF in the west of the deposit. This is a result of the model extrapolating the occurrence of high sulfur material to surface based on the mineralisation following the sub vertical dip of the geology. Given the low levels of sulfur noted in the Oxide from testing to date, this assumption is not likely to be realistic as the Oxide material represents a zone of oxidised material which has been depleted in reactive sulfides.

The eventual product/waste stream the PAF materials may report to (i.e. waste rock/ore), and a determination as to whether these materials will be mined will depend on the eventual classification of these materials as waste or ore within the mine model, and final pit levels. The volume of PAF material projected to report to the waste rock dump should therefore be revised once the resource model has been completed. Additional drilling that may be carried out at the site as part of resource definition, and grade control works during mining will enable the volume of PAF material to be more accurately defined in the resource model.

The modelled volume of PAF has been estimated based on current drilling data to be 26,592,500 m^3. The modelling carried out utilised high resolution block size with blocks of 2m in vertical extent and 25m lateral extent. At this time the mining process anticipated to be utilised at the site will involve drill and blast techniques with bench heights of 10m. Due to of the bulk mining process proposed, and the localised nature (and vertical extent) of PAF material identified, it is unlikely that the localised area(s) of PAF material will be able to be practically identified and segregated during mining works, particularly in the BIF material.

A summary geochemical classification of potential waste materials based on the analysis data presented herein is provided in Table 21:

Table 21 Preliminary waste material classifications

Lithology type	**PAF/NAF classification**	**Significant Sub classification (minor if any >1%, major if >10%)**
BIF-South	NAF	Minor PAF
		Major NAC
BIF-North	NAF	Minor NAC
		Minor PAF
Hanging Wall	NAF/PAF	Major PAF
Footwall	NAF/PAF	Minor PAF
Oxide	NAF	
Waste stream	**PAF/NAF classification**	**Significant Sub classification (if any)**
*Tailings (dry)	NAF/NAC	Minor PAF
		Major NAC
*Tailings (wet)	NAF/NAC	Minor PAF
		Major NAC
*Waste rock	NAF/PAF	Major PAF

*It should be noted that the classification of materials in each waste stream is highly dependent upon the designation of materials as waste or ore within the mine model. It is currently assumed that the ore body comprises the BIF units only, and that the Hanging Wall and Footwall are waste units. If the Hanging Wall or Footwall materials are processed as ore they will report to the tailings waste stream which will significantly alter the classifications given in Table 21.

9.7 Further Detailed Testing Planned

To confirm the provisional classification criteria adopted to date on this project a programme of additional geochemical testing has been scheduled to be carried out to include:

- Kinetic column leach testing has been scheduled to be carried out on a number of samples:
    - Samples of PAF material form the Hanging Wall to determine reaction rates with respect to sulfide oxidation;
    - Samples of BIF South that have NAPP values of 15-20 kg H_2SO_4/t to determine if it is appropriate to increase the PAF cut off to 20 kg H_2SO_4/t;
    - Samples of BIF, Hanging Wall and Footwall with NAPP values between 0-10 kg H_2SO_4/t to confirm that this material is NAF;
    - Sample of the dry tailing sto confirm if this material is NAF; and
    - A blend of two parts of dry tailings to one part PAF material, to determine if the tailings are a suitable neutralising agent.

A sampling and analysis plan for the additional testing is provided in Appendix H.
